Chapter 1

G_0W_0 Derivations: 11/9

1.1 Deriving Hedin's equations

1.1.1 Time-Domain Definition of the Green's Function

Start by considering the equation of motion for the field operators

$$i\frac{\partial}{\partial t}\hat{\psi}(\mathbf{x}, t) = [\hat{\psi}(\mathbf{x}, t), \hat{H}_{elec}] = [\hat{\psi}(\mathbf{x}, t), \hat{H}_0 + \hat{H}_{int}] = [\hat{\psi}(\mathbf{x}, t), \hat{H}_0] + [\hat{\psi}(\mathbf{x}, t), \hat{H}_{int}] \quad (1.1)$$

For the non-interacting part, we have

$$[\hat{\psi}(\mathbf{x}, t), \hat{H}_0] = [\hat{\psi}(\mathbf{x}, t), \int d\mathbf{x}' \hat{\psi}^\dagger(\mathbf{x}', t) \hat{h}^0(\mathbf{x}') \hat{\psi}(\mathbf{x}', t)] \quad (1.2)$$

$$= \int d\mathbf{x}' [\hat{\psi}(\mathbf{x}, t), \hat{\psi}^\dagger(\mathbf{x}', t) \hat{h}^0(\mathbf{x}') \hat{\psi}(\mathbf{x}', t)] \quad (1.3)$$

$$= \int d\mathbf{x}' \left(\underbrace{[\hat{\psi}(\mathbf{x}, t), \hat{\psi}^\dagger(\mathbf{x}', t)]}_{\delta(\mathbf{x}-\mathbf{x}')} \hat{h}^0(\mathbf{x}') \hat{\psi}(\mathbf{x}', t) + \hat{\psi}^\dagger(\mathbf{x}', t) \hat{h}^0(\mathbf{x}') \underbrace{[\hat{\psi}(\mathbf{x}, t), \hat{\psi}(\mathbf{x}', t)]}_0 \right) \quad (1.4)$$

$$= \hat{h}^0(\mathbf{x}) \hat{\psi}(\mathbf{x}, t). \quad (1.5)$$

For the interacting part, we have

$$[\hat{\psi}(\mathbf{x}, t), \hat{H}_{int}] = \frac{1}{2} \int d\mathbf{x}' d\mathbf{x}'' v(\mathbf{x}, \mathbf{x}') [\hat{\psi}(\mathbf{x}, t), \hat{\psi}^\dagger(\mathbf{x}', t) \hat{\psi}^\dagger(\mathbf{x}'', t) \hat{\psi}(\mathbf{x}'', t) \hat{\psi}(\mathbf{x}', t)] \quad (1.6)$$

$$= \frac{1}{2} \int d\mathbf{x}' d\mathbf{x}'' v(\mathbf{x}, \mathbf{x}') \left(\delta(\mathbf{x} - \mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}'', t) \hat{\psi}(\mathbf{x}'', t) \hat{\psi}(\mathbf{x}', t) + \hat{\psi}^\dagger(\mathbf{x}', t) \delta(\mathbf{x} - \mathbf{x}'') \hat{\psi}(\mathbf{x}'', t) \hat{\psi}(\mathbf{x}', t) \right) \quad (1.7)$$

$$= \int d\mathbf{x}' \hat{\psi}^\dagger(\mathbf{x}', t) v(\mathbf{x}, \mathbf{x}') \hat{\psi}(\mathbf{x}', t) \hat{\psi}(\mathbf{x}, t) \quad (1.8)$$

so overall we have

$$i\frac{\partial}{\partial t}\hat{\psi}(\mathbf{x}, t) = \left(\hat{h}^0(\mathbf{x}) + \int d\mathbf{x}' v(\mathbf{x}, \mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}', t) \hat{\psi}(\mathbf{x}', t) \right) \hat{\psi}(\mathbf{x}, t) \quad (1.9)$$

Now we can consider the equation of motion for the Green's function, defined as $G(\mathbf{x}t, \mathbf{x}'t') = -i \langle N | \mathcal{T} \left(\hat{\psi}(\mathbf{x}, t) \hat{\psi}^\dagger(\mathbf{x}', t') \right) | N \rangle$, where \mathcal{T} is the time-ordering operator.

$$\frac{\partial}{\partial t} G(\mathbf{x}t, \mathbf{x}'t') = -i \langle N | \frac{\partial}{\partial t} \mathcal{T} \left(\hat{\psi}(\mathbf{x}, t) \hat{\psi}^\dagger(\mathbf{x}', t') \right) | N \rangle \quad (1.10)$$

$$(1.11)$$

Now,

$$\frac{\partial}{\partial t} \mathcal{T} \left(\hat{\psi}(\mathbf{x}, t) \hat{\psi}^\dagger(\mathbf{x}', t') \right) = \frac{\partial}{\partial t} \left(\theta(t - t') \hat{\psi}(\mathbf{x}, t) \hat{\psi}^\dagger(\mathbf{x}', t') - \theta(t' - t) \hat{\psi}^\dagger(\mathbf{x}', t') \hat{\psi}(\mathbf{x}, t) \right) \quad (1.12)$$

$$= \underbrace{\frac{\partial \theta(t - t')}{\partial t}}_{\delta(t - t')} \hat{\psi}(\mathbf{x}, t) \hat{\psi}^\dagger(\mathbf{x}', t') + \theta(t - t') \frac{\partial}{\partial t} \hat{\psi}(\mathbf{x}, t) \hat{\psi}^\dagger(\mathbf{x}', t') - \underbrace{\frac{\partial \theta(t' - t)}{\partial t}}_{-\delta(t' - t)} \hat{\psi}^\dagger(\mathbf{x}', t') \hat{\psi}(\mathbf{x}, t) - \theta(t' - t) \frac{\partial}{\partial t} \hat{\psi}^\dagger(\mathbf{x}', t') \quad (1.13)$$

$$= \underbrace{\delta(t - t') \left\{ \hat{\psi}(\mathbf{x}, t), \hat{\psi}^\dagger(\mathbf{x}', t') \right\}}_{\delta(\mathbf{x} - \mathbf{x}') \delta(t - t')} + \mathcal{T} \left(\frac{\partial}{\partial t} \hat{\psi}(\mathbf{x}, t) \hat{\psi}^\dagger(\mathbf{x}', t') \right) \quad (1.14)$$

$$(1.15)$$

So now consider plugging in the equation of motion for $\hat{\psi}(\mathbf{x}, t)$ into the above expression

$$\mathcal{T} \left(\frac{\partial}{\partial t} \hat{\psi}(\mathbf{x}, t) \hat{\psi}^\dagger(\mathbf{x}', t') \right) = \mathcal{T} \left(-i \left(\hat{h}^0(\mathbf{x}) + \int d\mathbf{x}'' v(\mathbf{x}, \mathbf{x}'') \hat{\psi}^\dagger(\mathbf{x}'', t) \hat{\psi}(\mathbf{x}'', t) \right) \hat{\psi}(\mathbf{x}, t) \hat{\psi}^\dagger(\mathbf{x}', t') \right) \quad (1.16)$$

$$= -i \hat{h}^0(\mathbf{x}) \mathcal{T} \left(\hat{\psi}(\mathbf{x}, t) \hat{\psi}^\dagger(\mathbf{x}', t') \right) - i \int d\mathbf{x}'' v(\mathbf{x}, \mathbf{x}'') \mathcal{T} \left(\hat{\psi}(\mathbf{x}, t) \hat{\psi}^\dagger(\mathbf{x}'', t) \hat{\psi}(\mathbf{x}'', t) \hat{\psi}^\dagger(\mathbf{x}', t') \right) \quad (1.17)$$

So we have

$$\left[i \frac{\partial}{\partial t} - \hat{h}^0(\mathbf{x}) \right] G(\mathbf{x}t, \mathbf{x}'t') = \delta(\mathbf{x} - \mathbf{x}') \delta(t - t') - i \int d\mathbf{x}'' v(\mathbf{x}, \mathbf{x}'') \underbrace{G_2(\mathbf{x}t, \mathbf{x}''t, \mathbf{x}'t^+, \mathbf{x}'t')}_{\langle N | \mathcal{T} \left(\hat{\psi}(\mathbf{x}, t) \hat{\psi}(\mathbf{x}'', t) \hat{\psi}^\dagger(\mathbf{x}'', t') \hat{\psi}^\dagger(\mathbf{x}', t') \right) | N \rangle} \quad (1.18)$$

and we notice that in order to compute the single-particle Green's function, we need to know the two-particle Green's function, which needs the three-particle Green's function, and so on. So to simplify we introduce a nonlocal, time-dependent self-energy $\Sigma(\mathbf{x}t, \mathbf{x}'t')$ that satisfies

$$-i \int d\mathbf{x}'' v(\mathbf{x}, \mathbf{x}'') G_2(\mathbf{x}t, \mathbf{x}''t, \mathbf{x}'t^+, \mathbf{x}'t') \equiv \int dt'' \int d\mathbf{x}'' \bar{\Sigma}(\mathbf{x}t, \mathbf{x}''t'') G(\mathbf{x}''t'', \mathbf{x}'t') \quad (1.19)$$

and further define $\Sigma = \bar{\Sigma} - v_H$ with

$$v_H(\mathbf{x}, t) = \int d\mathbf{x}' v(\mathbf{x}, \mathbf{x}') \underbrace{\langle N | \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}(\mathbf{x}') | N \rangle}_{-\frac{1}{i} G(\mathbf{x}'t, \mathbf{x}'t)} = i \int d\mathbf{x}' v(\mathbf{x}, \mathbf{x}') G(\mathbf{x}'t, \mathbf{x}'t) \quad (1.20)$$

and we can rewrite the equation of motion as

$$\left[i \frac{\partial}{\partial t} - \hat{h}^0(\mathbf{x}) - v_H(\mathbf{x}, t) \right] G(\mathbf{x}t, \mathbf{x}'t') = \delta(\mathbf{x} - \mathbf{x}')\delta(t - t') + \int dt'' \int d\mathbf{x}'' \Sigma(\mathbf{x}t, \mathbf{x}''t'') G(\mathbf{x}''t'', \mathbf{x}'t') \quad (1.21)$$

Now consider defining the G_0 of the non-interacting system

$$\left[i \frac{\partial}{\partial t} - \hat{h}^0(\mathbf{x}) - v_H(\mathbf{x}, t) \right] G_0(\mathbf{x}t, \mathbf{x}'t') = \delta(\mathbf{x} - \mathbf{x}')\delta(t - t') \quad (1.22)$$

So we can write equations 1.21 and 1.22 symbolically as

$$\hat{O}G = \delta + \Sigma G \quad \text{and} \quad \hat{O}G_0 = \delta \quad (1.23)$$

$$\implies G_0 = \hat{O}^{-1} \implies G = G_0 + G_0 \Sigma G \quad (1.24)$$

$$\implies G(1, 2) = G_0(1, 2) + \int d3d4 G_0(1, 3) \Sigma(3, 4) G(4, 2) \quad (1.25)$$

where we use the space-time notation $1 = (\mathbf{x}_1, t_1)$ etc.

1.1.2 Hedin's Equations

Schwinger chose to introduce a potential φ that we will later set to zero, in order to rewrite the two-particle Green's function as

$$G_2(1, 3, 2, 3^+) = G(1, 2) G(3, 3^+) - \frac{\delta G(1, 2)}{\delta \varphi(3)}, \quad (1.26)$$

So

$$\bar{\Sigma}(1, 2) = -i \int d(3) v(1, 3) G_2(1, 3, 2, 3^+) \quad (1.27)$$

$$= -i \int d(3) v(1, 3) \left[G(1, 2) G(3, 3^+) - \frac{\delta G(1, 2)}{\delta \varphi(3)} \right] \quad (1.28)$$

$$= -i G(1, 2) \underbrace{\int d(3) v(1, 3) G(3, 3^+)}_{-iv_H(1)} + i \int d(3) v(1, 3) \frac{\delta G(1, 2)}{\delta \varphi(3)}. \quad (1.29)$$

Now because $\delta G = -G(\delta G^{-1})G$ we can write the identity

$$\frac{\delta G(1, 2)}{\delta \varphi(3)} = - \int d(4)d(5) G(1, 4) \frac{\delta G^{-1}(4, 5)}{\delta \varphi(3)} G(5, 2). \quad (1.30)$$

So the second term in Eq. (1.29) gives

$$\begin{aligned} i \int d(3) v(1, 3) \frac{\delta G(1, 2)}{\delta \varphi(3)} &= -i \int d(3) v(1, 3) \int d(4)d(5) G(1, 4) \frac{\delta G^{-1}(4, 5)}{\delta \varphi(3)} G(5, 2) \\ &= -i \int d(3, 4, 5) v(1, 3) G(1, 4) \frac{\delta G^{-1}(4, 5)}{\delta \varphi(3)} G(5, 2). \end{aligned} \quad (1.31)$$

Now we can get rid of a $G(1, 2)$ dependence by multiplying with G^{-1} , yielding

$$\bar{\Sigma}(1, 2) = -\delta(1, 2) v_H(1) - i \int d(3, 4) v(1, 3) G(1, 4) \frac{\delta G^{-1}(4, 2)}{\delta \varphi(3)}. \quad (1.32)$$

Introduce $V(1) = \varphi(1) + v_H(1)$ as the total potential that electrons experience. Consider

$$\frac{\delta G^{-1}(1, 2)}{\delta \varphi(3)} \equiv \underbrace{\frac{\delta G^{-1}(1, 2)}{\delta V(5)}}_{-\Gamma(1, 2, 5)} \underbrace{\frac{\delta V(5)}{\delta \varphi(3)}}_{\varepsilon^{-1}(5, 3)}. \quad (1.33)$$

So

$$\bar{\Sigma}(1, 2) = -\delta(1, 2) v_H(1) + i \underbrace{\int d(5) \int d(3) v(1, 3) \varepsilon^{-1}(3, 5)}_{W(1, 5)} \int d(4) G(1, 4) \Gamma(4, 5, 2). \quad (1.34)$$

and if we further make the GW approximation where $\Gamma(4, 5, 2) \approx \delta(4, 5) \delta(2, 5)$ we get

$$\bar{\Sigma}(1, 2) = -\delta(1, 2) v_H(1) + i W(1, 2) G(1, 2) \quad (1.35)$$

and if we just care about the exchange-correlation part, we can define

$$\Sigma_{xc}(1, 2) = \bar{\Sigma}(1, 2) + \delta(1, 2) v_H(1) = i W(1, 2) G(1, 2) \implies \Sigma_{xc}(\tau) = i W(\tau) G(\tau) \quad (1.36)$$

where $\tau = t_1 - t_2$. Define $G(\tau) = \int \frac{d\omega'}{2\pi} e^{-i\omega'\tau} G(\omega')$ and $W(\tau) = \int \frac{d\omega''}{2\pi} e^{-i\omega''\tau} W(\omega'')$ to get

$$\Sigma_{xc}(\tau) = i \int \frac{d\omega'}{2\pi} \int \frac{d\omega''}{2\pi} e^{-i(\omega' + \omega'')\tau} G(\omega') W(\omega'') \quad (1.37)$$

Taking the inverse Fourier transform of $\Sigma_{xc}(\tau)$ we get

$$\Sigma_{xc}(\omega) = \int \frac{d\tau}{2\pi} e^{i\omega\tau} \Sigma_{xc}(\tau) = i \int \frac{d\omega'}{2\pi} \int \frac{d\omega''}{2\pi} G(\omega') W(\omega'') \underbrace{\int d\tau e^{i(\omega - \omega' - \omega'')\tau}}_{2\pi\delta(\omega - \omega' - \omega'')} = i \int \frac{d\omega'}{2\pi} G(\omega') W(\omega - \omega') \quad (1.38)$$

Now in G_0W_0 one applies the Cauchy residue theorem to solve this convolution integral, yielding the known form.

1.2 Final expressions

1.2.1 Fully analytic

I follow the notation of Tianyu's paper throughout this section [?]. We want to solve for the self-energy whose form along the real axis is:

$$\Sigma(\mathbf{r}, \mathbf{r}', \omega) = \frac{i}{2\pi} \int_{-\infty}^{\infty} e^{i\omega'\eta} d\omega' G_0(\mathbf{r}, \mathbf{r}', \omega + \omega') W_0(\mathbf{r}, \mathbf{r}', \omega') \quad (1.39)$$

In the molecular brutal basis, the self energy is given as:

$$\Sigma_{nn'}(\mathbf{k}, \omega) = \iint d\mathbf{r}d\mathbf{r}' \psi_{n\mathbf{k}}^*(\mathbf{r}) \Sigma(\mathbf{r}, \mathbf{r}', \omega) \psi_{n'\mathbf{k}}(\mathbf{r}') \quad (1.40)$$

Also, recall that the Lehmann representation of the noninteracting Green's function is:

$$G_0(\mathbf{r}, \mathbf{r}', \omega) = \sum_{o\mathbf{q}} \frac{\psi_{o\mathbf{q}}(\mathbf{r}) \psi_{o\mathbf{q}}^*(\mathbf{r}')}{\omega - \epsilon_{o\mathbf{q}} + i\eta \operatorname{sgn}(\epsilon_{o\mathbf{q}} - \mu)} \quad (1.41)$$

Now plugging both of these back into the original expression, we find:

$$\begin{aligned} \Sigma_{nn'}(\mathbf{k}, \omega) &= \frac{i}{2\pi} \sum_{o\mathbf{q}} \int_{-\infty}^{\infty} d\omega' \frac{e^{i\omega'\eta}}{\omega + \omega' - \epsilon_{o\mathbf{q}} + i\eta \operatorname{sgn}(\epsilon_{o\mathbf{q}} - \mu)} \\ &\quad \times \iint d\mathbf{r}d\mathbf{r}' \psi_{n\mathbf{k}}^*(\mathbf{r}) \psi_{o\mathbf{q}}(\mathbf{r}) W_0(\mathbf{r}, \mathbf{r}', \omega') \psi_{o\mathbf{q}}^*(\mathbf{r}') \psi_{n'\mathbf{k}}(\mathbf{r}') \end{aligned} \quad (1.42)$$

$$= \frac{i}{2\pi} \sum_{o\mathbf{q}} \int_{-\infty}^{\infty} d\omega' \frac{e^{i\omega'\eta}}{\omega + \omega' - \epsilon_{o\mathbf{k}-\mathbf{q}} + i\eta \operatorname{sgn}(\epsilon_{o\mathbf{k}-\mathbf{q}} - \mu)} (n_{\mathbf{k}o\mathbf{k}-\mathbf{q}} | W_0 | o_{\mathbf{k}-\mathbf{q}} n'_{\mathbf{k}}) \quad (1.43)$$

Where we have used the fact that the momentum index \mathbf{q} is the same as $\mathbf{k} - \mathbf{q}$, given that we are looping over both \mathbf{k} and \mathbf{q} anyways.

So the Green's function will bring poles at $\omega' = \epsilon_{o\mathbf{k}-\mathbf{q}} - \omega + i\eta \operatorname{sgn}(\mu - \epsilon_{o\mathbf{k}-\mathbf{q}})$. Now, we know that the screened Coulomb interaction has the expansion in terms of the bare Coulomb potential v and the density response function χ_0 as $W_0 = v + v\chi_0v + v\chi_0v\chi_0v + \dots = v(1 + \chi_0v + \chi_0v\chi_0v + \dots) = v(1 - \chi_0v)^{-1}$, where we recognize the dielectric function as $\epsilon_0 = 1 - \chi_0v$ so we can express the screened Coulomb interaction as

$$W_0(\mathbf{r}, \mathbf{r}', \omega) = \frac{v(\mathbf{r}, \mathbf{r}')}{1 - (\chi_0v)(\mathbf{r}, \mathbf{r}', \omega)} \quad (1.44)$$

recalling that the bare Coulomb interaction should be independent of frequency. A discussion of how to compute the screened Coulomb interaction can be found in this old work [?]. To simplify notation let us define a polarizability $\Pi(\mathbf{r}, \mathbf{r}', \omega) = (\chi_0v)(\mathbf{r}, \mathbf{r}', \omega)$, so that we can rewrite the screened Coulomb interaction as:

$$(n_{\mathbf{k}o\mathbf{k}-\mathbf{q}} | W_0 | o_{\mathbf{k}-\mathbf{q}} n'_{\mathbf{k}}) = \iint d\mathbf{r}d\mathbf{r}' \psi_{n\mathbf{k}}^*(\mathbf{r}) \psi_{o\mathbf{q}}(\mathbf{r}) W_0(\omega) \psi_{o\mathbf{q}}^*(\mathbf{r}') \psi_{n'\mathbf{k}}(\mathbf{r}') \quad (1.45)$$

At this point, we recognize the decomposition of the ERIs with the Cholesky vectors as:

$$(p_{\mathbf{k}_p} q_{\mathbf{k}_q} | \frac{1}{|\mathbf{r} - \mathbf{r}'|} | r_{\mathbf{k}_r} s_{\mathbf{k}_s}) = \sum_{PQ} v_{P\mathbf{q}}^{p_{\mathbf{k}_p} q_{\mathbf{k}_q}} v_{Q(-\mathbf{q})}^{r_{\mathbf{k}_r} s_{\mathbf{k}_s}} \quad (1.46)$$

so each Cholesky brings a factor of $\mathbf{J}^{\frac{1}{2}}$. Each Cholesky is defined as:

$$v_{P\mathbf{q}}^{p_{\mathbf{k}_p} q_{\mathbf{k}_q}} = \sum_R \mathbf{J}_{RP}^{-\frac{1}{2}}(\mathbf{q}) (R\mathbf{q} | p_{\mathbf{k}_p} q_{\mathbf{k}_q}) \quad (1.47)$$

where

$$\begin{aligned} \mathbf{J}_{PQ}(\mathbf{k}) &= \iint d\mathbf{r} d\mathbf{r}' \phi_{P(-\mathbf{k})}(\mathbf{r}) \frac{1}{|\mathbf{r} - \mathbf{r}'|} \phi_{Q\mathbf{k}}(\mathbf{r}') \\ (Q\mathbf{k}_{rs} | r\mathbf{k}_r s\mathbf{k}_s) &= \iint d\mathbf{r} d\mathbf{r}' \phi_{Q\mathbf{k}_{rs}}(\mathbf{r}) \frac{1}{|\mathbf{r} - \mathbf{r}'|} \phi_{r\mathbf{k}_r}^*(\mathbf{r}') \phi_{s\mathbf{k}_s}(\mathbf{r}') \end{aligned} \quad (1.48)$$

So the simplest thing now will be to derive an expression for the columb interaction in terms of an auxiliary basis:

$$W_{0,PQ}(\omega) = [\mathbf{J}(\mathbf{I} - \mathbf{\Pi}(\mathbf{q}, \omega))^{-1}]_{PQ} \quad (1.49)$$

and then we need to contract with the Choleskies to get the matrix element:

$$(n_{\mathbf{k}} o_{\mathbf{k}-\mathbf{q}} | W_0 | o_{\mathbf{k}-\mathbf{q}} n'_{\mathbf{k}}) = \sum_{PQ} v_P^{nm} [\mathbf{I} - \mathbf{\Pi}(\mathbf{q}, \omega)]_{PQ}^{-1} v_Q^{mn'} \quad (1.50)$$

So in our quest to find poles of W_0 , we are really just looking for poles of the χ_0 . χ_0 is given by:

$$\chi_0(\mathbf{r}, \mathbf{r}', \omega) = \sum_{r\mathbf{k} s\mathbf{k}'} (f_{r\mathbf{k}} - f_{s\mathbf{k}'}) \frac{\psi_{r\mathbf{k}}(\mathbf{r}) \psi_{r\mathbf{k}}^*(\mathbf{r}') \psi_{s\mathbf{k}'}(\mathbf{r}') \psi_{s\mathbf{k}'}^*(\mathbf{r})}{\omega - (\epsilon_{r\mathbf{k}} - \epsilon_{s\mathbf{k}'}) + i\eta \operatorname{sgn}(\epsilon_{r\mathbf{k}} - \epsilon_{s\mathbf{k}'} - \mu)} \quad (1.51)$$

where the occupations of the KS states $r\mathbf{k}(s\mathbf{k}')$ with energies $\epsilon_{r\mathbf{k}}(\epsilon_{s\mathbf{k}'})$ are given by the Fermi-Dirac distribution $f_{r\mathbf{k}}(f_{s\mathbf{k}'})$, which is just a step function at zero temperature. Notice that the occupation factor will always be 0 unless rs form an occupied-virtual pair. So we can separate the density response into two terms, one where δ_{ri} and δ_{sa} and the other with δ_{ra} and δ_{si} , where i and a are occupied and virtual indices, respectively. This allows us to now combine with the bare Coulomb potential in order to form the polarizability $\Pi \equiv \chi_0 v$ as:

$$\Pi(\mathbf{r}, \mathbf{r}', \omega) = \sum_{i\mathbf{k} a\mathbf{k}'} \frac{\psi_{i\mathbf{k}}(\mathbf{r}) \psi_{i\mathbf{k}}^*(\mathbf{r}') \frac{1}{|\mathbf{r}-\mathbf{r}'|} \psi_{a\mathbf{k}'}(\mathbf{r}') \psi_{a\mathbf{k}'}^*(\mathbf{r})}{\omega + (\Omega_{i\mathbf{k} a\mathbf{k}'} - i\eta)} - \sum_{a\mathbf{i} \mathbf{k}\mathbf{k}'} \frac{\psi_{a\mathbf{k}}(\mathbf{r}) \psi_{a\mathbf{k}}^*(\mathbf{r}') \frac{1}{|\mathbf{r}-\mathbf{r}'|} \psi_{i\mathbf{k}'}(\mathbf{r}') \psi_{i\mathbf{k}'}^*(\mathbf{r})}{\omega - (\Omega_{i\mathbf{k} a\mathbf{k}'} + i\eta)}, \quad (1.52)$$

where we define the KS eigenvalue differences as $\Omega_{i\mathbf{k} a\mathbf{k}'} = \epsilon_{a\mathbf{k}} - \epsilon_{i\mathbf{k}'}$, which will eventually become the excitation energies from RPA. So sandwiching this operator in between the molecular or brutal bases gives:

$$\langle n\mathbf{k} | \Pi(\omega) | n'\mathbf{k} \rangle = \sum_{iajb\mathbf{k}\mathbf{k}'} \frac{(ia | jb)}{(\omega + \Omega_{\mathbf{k}}^\mu - i\eta)} - \sum_{aibj\mathbf{k}\mathbf{k}'} \frac{(ai | bj)}{(\omega - \Omega_{\mathbf{k}}^\mu + i\eta)} \quad (1.53)$$

So we see that we can get the poles of the screened Coulomb interaction by the poles of the polarizability, which are $\omega = \Omega_{\mathbf{k}}^\mu - i\eta$ and $\omega = \Omega_{\mathbf{k}}^\mu + i\eta$, suggesting that they are in the upper complex plane for excitations and vice versa for deexcitations. See the figure 1.1 for a picture. For a more comprehensive picture, this should be juxtaposed with the figure from Tianyu's paper for CD. In the literature, they talk about approximating the dielectric function by a multiple one or a single pole approximation, so which one would I want to implement? This suggests that the notation in the G_0W_0 literature is confusing because they always say that to solve for the χ_0 in the RPA, but if we are actually dealing with χ_0 , which is the Kohn-Sham density response function, then we don't use the RPA, where the density response function is solved for using a Dyson-like equation [?]:

Figure 1.1: Contour for the complex frequency integral. The poles are denoted by the various ω . The Fermi energy is denoted by ε_F . The integration contour D_+ is the semicircle in the upper complex plane, while D_- is the semicircle in the lower complex plane.

$$\chi^\lambda(\mathbf{r}, \mathbf{r}', i\omega) = \chi^0(\mathbf{r}, \mathbf{r}', i\omega) + \int d\mathbf{r}_1 d\mathbf{r}_2 \chi^0(\mathbf{r}, \mathbf{r}_1, i\omega) \left[\frac{\lambda}{|\mathbf{r}_1 - \mathbf{r}_2|} + f_{\text{xc}}^\lambda(\mathbf{r}_1, \mathbf{r}_2, i\omega) \right] \chi^\lambda(\mathbf{r}_2, \mathbf{r}', \omega) \quad (1.54)$$

where the parameter λ controls the amount of interaction in the system, ranging from $\lambda = 0$ for the KS reference system to $\lambda = 1$ for the fully interacting system. The f_{xc}^λ is the exchange-correlation kernel, which is set to zero for the RPA. But we will proceed with an RPA calculation anyways in order to solve for the excitation energies and their corresponding eigenvectors. So it makes sense that the numerator of the expression for the screened Coulomb interaction should be given a construction of the ERIs with the excitation factors in a transition density defined as:

$$w_{pq}^\mu = \sum_{ia} (pq|ia) (X_{ia}^\mu + Y_{ai}^\mu) \quad (1.55)$$

where we have defined the excitation and de-excitation vectors at the excitation index μ as X_{ia}^μ and Y_{ai}^μ , respectively. I am not sure how to connect this with the known expression $v\epsilon^{-1}$; I see the similarities given that we are contracting an ERI with what we get from the RPA calculation that is connected to the polarizability, but can't connect exactly. We want to figure out how this matches with my previous $O(N^6)$ expression, which was

$$\Sigma_{pp}^{\text{corr}}(\omega) = \sum_{\mu}^{\text{RPA}} \left(\sum_i^{\text{occupied}} \frac{w_{pi}^\mu w_{ip}^\mu}{\omega - (\epsilon_i - \Omega_\mu)} + \sum_a^{\text{virtual}} \frac{w_{pa}^\mu w_{ap}^\mu}{\omega - (\epsilon_a + \Omega_\mu)} \right) \quad (1.56)$$

for the molecular case. Today I want us to dissect how this equation came about, so that I can understand for my k-point version.

1.2.2 Analytic continuation

We start with the original form for the self-energy along the real axis:

$$\Sigma(\mathbf{r}, \mathbf{r}', \omega) = \frac{i}{2\pi} \int_{-\infty}^{\infty} d\omega' e^{i\omega'\eta} G_0(\mathbf{r}, \mathbf{r}', \omega + \omega') W_0(\mathbf{r}, \mathbf{r}', \omega') \quad (1.57)$$

But to avoid the poles, we need to evaluate along the imaginary axis, so the problem becomes:

$$\Sigma(\mathbf{r}, \mathbf{r}', i\omega) = -\frac{1}{2\pi} \int_{-\infty}^{\infty} d\omega' G_0(\mathbf{r}, \mathbf{r}', i\omega + i\omega') W_0(\mathbf{r}, \mathbf{r}', i\omega')$$

We are interested in evaluating the matrix elements of this operator in the molecular orbital basis. Note that both molecular orbitals must have the same crystal momentum in order for it to be conserved in this process. We also apply the identity operator:

$$\langle n\mathbf{k} | \Sigma(i\omega) | n'\mathbf{k} \rangle = -\frac{1}{2\pi} \sum_{m\mathbf{k}'} \int_{-\infty}^{\infty} d\omega' \langle n\mathbf{k} | G_0(i\omega + i\omega') | m\mathbf{k}' \rangle \langle m\mathbf{k}' | W_0(i\omega') | n'\mathbf{k} \rangle \quad (1.58)$$

The noninteracting Green's function has the form:

$$G_0(\mathbf{r}, \mathbf{r}', i\omega) = \sum_{m\mathbf{k}_m} \frac{\psi_{m\mathbf{k}_m}(\mathbf{r}) \psi_{m\mathbf{k}_m}^*(\mathbf{r}')}{i\omega + \epsilon_F - \epsilon_{m\mathbf{k}_m}} \implies G_0(\mathbf{k} - \mathbf{q}, i\omega + i\omega') = \sum_{m\mathbf{k}-\mathbf{q}} \frac{\psi_{m\mathbf{k}-\mathbf{q}} \psi_{m\mathbf{k}-\mathbf{q}}^*}{i(\omega + \omega') + \epsilon_F - \epsilon_{m\mathbf{k}-\mathbf{q}}}$$

so that the above equation simplifies to:

$$\Sigma_{nn'}(\mathbf{k}, i\omega) = -\frac{1}{2\pi N_{\mathbf{k}}} \sum_{m\mathbf{q}} \int_{-\infty}^{\infty} d\omega' \frac{(n\mathbf{k}, m\mathbf{k} - \mathbf{q} | W_0(\mathbf{q}, i\omega) | m\mathbf{k} - \mathbf{q}, n'\mathbf{k})}{i(\omega + \omega') + \epsilon_F - \epsilon_{m\mathbf{k}-\mathbf{q}}} \quad (1.59)$$

Screened Coulomb Interaction

$$(n\mathbf{k}, m\mathbf{k} - \mathbf{q} | W_0(\mathbf{q}, i\omega) | m\mathbf{k} - \mathbf{q}, n'\mathbf{k}) = \int \int d\mathbf{r}_1 d\mathbf{r}_2 \psi_{n\mathbf{k}}^*(\mathbf{r}_1) \psi_{m\mathbf{k}-\mathbf{q}}(\mathbf{r}_1) W_0(\mathbf{q}, \mathbf{r}_1, \mathbf{r}_2, i\omega) \psi_{m\mathbf{k}-\mathbf{q}}^*(\mathbf{r}_2) \psi_{n'\mathbf{k}}(\mathbf{r}_2)$$

We expand the orbital pair product $\psi_{n\mathbf{k}}^*(\mathbf{r}) \psi_{m\mathbf{k}-\mathbf{q}}(\mathbf{r})$ in the auxiliary basis

$$\psi_{n\mathbf{k}}^*(\mathbf{r}) \psi_{m\mathbf{k}-\mathbf{q}}(\mathbf{r}) = \sum_P b_{P\mathbf{q}}^{n\mathbf{k}, m\mathbf{k}-\mathbf{q}} \phi_{P\mathbf{q}}(\mathbf{r})$$

and

$$\psi_{m\mathbf{k}-\mathbf{q}}^*(\mathbf{r}) \psi_{n'\mathbf{k}}(\mathbf{r}) = \sum_Q b_{Q(-\mathbf{q})}^{m\mathbf{k}-\mathbf{q}, n'\mathbf{k}} \phi_{Q(-\mathbf{q})}(\mathbf{r}) \quad (1.60)$$

where we have recognized the fact that in the former there is a momentum transfer of \mathbf{q} , and in the latter, there is a momentum transfer of $-\mathbf{q}$. Substituting in gives

$$(n\mathbf{k}, m\mathbf{k} - \mathbf{q} | W_0(\mathbf{q}, i\omega) | m\mathbf{k} - \mathbf{q}, n'\mathbf{k}) \quad (1.61)$$

$$= \sum_{PQ} b_{P\mathbf{q}}^{n\mathbf{k}, m\mathbf{k} - \mathbf{q}} \left[\iint d\mathbf{r}_1 d\mathbf{r}_2 \phi_{P\mathbf{q}}(\mathbf{r}_1) W_0(\mathbf{q}, \mathbf{r}_1, \mathbf{r}_2, i\omega) \phi_{Q(-\mathbf{q})}(\mathbf{r}_2) \right] b_{Q(-\mathbf{q})}^{m\mathbf{k} - \mathbf{q}, n'\mathbf{k}} \quad (1.62)$$

with

$$b_{P\mathbf{q}}^{n\mathbf{k}, m\mathbf{k} - \mathbf{q}} = \sum_R (n\mathbf{k}, m\mathbf{k} - \mathbf{q} | R\mathbf{q}) \cdot \mathbf{J}_{RP}^{-1}(\mathbf{q}) \quad (1.63)$$

Now is a good place to recall their definition of the density fitting where the ERIs are represented as:

$$(p\mathbf{k}_p q\mathbf{k}_q | r\mathbf{k}_r s\mathbf{k}_s) = \sum_{PQ} (p\mathbf{k}_p q\mathbf{k}_q | P\mathbf{k}_{pq}) \mathbf{J}_{PQ}^{-1} (Q\mathbf{k}_{rs} | r\mathbf{k}_r s\mathbf{k}_s),$$

with

$$\begin{aligned} \mathbf{J}_{PQ}(\mathbf{k}) &= \iint d\mathbf{r} d\mathbf{r}' \phi_{P(-\mathbf{k})}(\mathbf{r}) \frac{1}{|\mathbf{r} - \mathbf{r}'|} \phi_{Q\mathbf{k}}(\mathbf{r}'), \\ (Q\mathbf{k}_{rs} | r\mathbf{k}_r s\mathbf{k}_s) &= \iint d\mathbf{r} d\mathbf{r}' \phi_{Q\mathbf{k}_{rs}}(\mathbf{r}) \frac{1}{|\mathbf{r} - \mathbf{r}'|} \phi_{r\mathbf{k}_r}^*(\mathbf{r}') \phi_{s\mathbf{k}_s}(\mathbf{r}'). \end{aligned}$$

Note that these b are then not yet our Cholesky vectors, since each one contains $\frac{|\mathbf{r} - \mathbf{r}'|}{|\mathbf{r} - \mathbf{r}'|}$ scaling, i.e., there should be a factor of $\mathbf{J}^{-\frac{1}{2}}$ instead of \mathbf{J}^{-1} in 1.63 if we are to apply the Cholesky vectors. At this point, we use the expansion of the screened Coulomb interaction:

$$W_0 = v + v\chi_0 v + v\chi_0 v\chi_0 v + \dots \quad (1.64)$$

$$= v(1 + \chi_0 v + \chi_0 v\chi_0 v + \dots) \quad (1.65)$$

$$= v^{1/2} (1 - \chi_0)^{-1} v^{1/2} \quad (1.66)$$

simplifying to

$$(n\mathbf{k}, m\mathbf{k} - \mathbf{q} | W_0(\mathbf{q}, i\omega) | m\mathbf{k} - \mathbf{q}, n'\mathbf{k}) = \sum_{PQ} b_{P\mathbf{q}}^{n\mathbf{k}, m\mathbf{k} - \mathbf{q}} \left[\mathbf{J}^{\frac{1}{2}} (\mathbf{I} - \mathbf{\Pi}(\mathbf{q}, i\omega)) \mathbf{J}^{\frac{1}{2}} \right]_{PQ}^{-1} b_{Q(-\mathbf{q})}^{m\mathbf{k} - \mathbf{q}, n'\mathbf{k}} \quad (1.67)$$

$$= \sum_{PQ} v_P^{nm} [\mathbf{I} - \mathbf{\Pi}(\mathbf{q}, i\omega')]_{PQ}^{-1} v_Q^{mn'} \quad (1.68)$$

where \mathbf{J}_{PQ} is the Coulomb interaction projected onto the auxiliary basis, and we have defined

$$v_{P\mathbf{q}}^{n\mathbf{k}, m\mathbf{k} - \mathbf{q}} = \sum_{pq} C_{pn}(\mathbf{k}) C_{qm}(\mathbf{k} - \mathbf{q}) v_{P\mathbf{q}}^{p\mathbf{k}, q\mathbf{k} - \mathbf{q}} \quad (1.69)$$

with

$$v_{P\mathbf{q}}^{p\mathbf{k}, q\mathbf{k} - \mathbf{q}} = \sum_R (p\mathbf{k}, q\mathbf{k} - \mathbf{q} | R\mathbf{q}) \mathbf{J}_{RP}^{-1/2}(\mathbf{q}) \quad (1.70)$$

If we first rename $\mathbf{k}' = \mathbf{k} - \mathbf{q} \implies \mathbf{k} = \mathbf{k}' + \mathbf{q}$, and then we are free to redefine $\mathbf{q} \rightarrow -\mathbf{q}$, so that 1.69 becomes

$$v_{P-\mathbf{q}}^{n\mathbf{k}-\mathbf{q},m\mathbf{k}} = \sum_{pq} C_{pn}(\mathbf{k} - \mathbf{q}) C_{qm}(\mathbf{k}) v_{P-\mathbf{q}}^{p\mathbf{k}-\mathbf{q},q\mathbf{k}} \quad (1.71)$$

but we know that the bare Coulomb potential projected onto the auxiliary basis is given by

$$v_{P\mathbf{q}}^{n\mathbf{k},m\mathbf{k}-\mathbf{q}} = \sum_{pq} C_{pn}(\mathbf{k}) C_{qm}(\mathbf{k} - \mathbf{q}) v_{P\mathbf{q}}^{p\mathbf{k},q\mathbf{k}-\mathbf{q}} \quad (1.72)$$

To ease notation, some momentum labels are suppressed in the above and following equations (e.g., we will use b_P^{nm} to denote $b_{P\mathbf{q}}^{n\mathbf{k},m\mathbf{k}-\mathbf{q}}$). Using Eqs. 19-21, the matrix elements of W_0 are computed as

$$\begin{aligned} & (n\mathbf{k}, m\mathbf{k} - \mathbf{q} | W_0 | m\mathbf{k} - \mathbf{q}, n'\mathbf{k}) \\ &= \sum_{PQ} b_P^{nm} \left[\iint d\mathbf{r} d\mathbf{r}' \phi_{P\mathbf{q}}(\mathbf{r}) W_0(\mathbf{r}, \mathbf{r}', i\omega') \phi_{Q(-\mathbf{q})}(\mathbf{r}') \right] b_Q^{mn'} \\ &= \sum_{PQ} b_P^{nm} \left[\mathbf{J}_{PQ}(\mathbf{q}) + (\mathbf{J}^{1/2} \mathbf{\Pi} \mathbf{J}^{1/2})_{PQ}(\mathbf{q}) + \dots \right] b_Q^{mn'} \\ &= \sum_{PQ} v_P^{nm} [\mathbf{I} - \mathbf{\Pi}(\mathbf{q}, i\omega')]_{PQ}^{-1} v_Q^{mn'} \end{aligned}$$

The 3-center 2-electron integral v_P^{nm} between auxiliary basis function P and molecular orbital pairs nm is obtained from an AO to MO transformation of the GDF AO integrals defined in Eq. 15:

$$v_P^{nm} = \sum_p \sum_q C_{pn}(\mathbf{k}) C_{qm}(\mathbf{k} - \mathbf{q}) v_{P\mathbf{q}}^{p\mathbf{k},q\mathbf{k}-\mathbf{q}}$$

where $C(\mathbf{k})$ refers to the MO coefficients in the AO basis. $\mathbf{\Pi}(\mathbf{q}, i\omega')$ in Eq. 22 is an auxiliary density response function:

$$\mathbf{\Pi}_{PQ}(\mathbf{q}, i\omega') = \frac{2}{N_{\mathbf{k}}} \sum_{\mathbf{k}} \sum_i^{\text{occ}} \sum_a^{\text{vir}} v_P^{ia} \frac{\epsilon_{i\mathbf{k}} - \epsilon_{a\mathbf{k}-\mathbf{q}}}{\omega'^2 + (\epsilon_{i\mathbf{k}} - \epsilon_{a\mathbf{k}-\mathbf{q}})^2} v_Q^{ai}$$

1.3 UHF formalism

The first thing to do is to solve the Casida equation for the polarizability in the direct formulation of the RPA:

$$\begin{pmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{B}^* & \mathbf{A}^* \end{pmatrix} \begin{pmatrix} \mathbf{X} \\ \mathbf{Y} \end{pmatrix} = \begin{pmatrix} \Omega & 0 \\ 0 & -\Omega \end{pmatrix} \begin{pmatrix} \mathbf{X} \\ \mathbf{Y} \end{pmatrix} \quad (1.73)$$

with \mathbf{A} and \mathbf{B} given by

$$\begin{aligned} \mathbf{A}_{ia,jb}^{\sigma\sigma'} &= \delta_{ij} \delta_{ab} \delta_{\sigma\sigma'} (\epsilon_a - \epsilon_i) + (i_{\sigma} a_{\sigma} | b_{\sigma'} j_{\sigma'}) \\ \mathbf{B}_{ia,jb}^{\sigma\sigma'} &= (i_{\sigma} a_{\sigma} | j_{\sigma'} b_{\sigma'}) \end{aligned} \quad (1.74)$$

Therefore, with the different spins we form a super matrix:

$$\begin{pmatrix} \begin{pmatrix} \mathbf{A}_{\alpha\alpha} & \mathbf{A}_{\alpha\beta} \\ \mathbf{A}_{\beta\alpha} & \mathbf{A}_{\beta\beta} \end{pmatrix} & \begin{pmatrix} \mathbf{B}_{\alpha\alpha} & \mathbf{B}_{\alpha\beta} \\ \mathbf{B}_{\beta\alpha} & \mathbf{B}_{\beta\beta} \end{pmatrix} \\ \begin{pmatrix} \mathbf{B}_{\alpha\alpha}^* & \mathbf{B}_{\alpha\beta}^* \\ \mathbf{B}_{\beta\alpha}^* & \mathbf{B}_{\beta\beta}^* \end{pmatrix} & \begin{pmatrix} \mathbf{A}_{\alpha\alpha}^* & \mathbf{A}_{\alpha\beta}^* \\ \mathbf{A}_{\beta\alpha}^* & \mathbf{A}_{\beta\beta}^* \end{pmatrix} \end{pmatrix} \begin{pmatrix} \mathbf{X}_{\alpha\alpha} & \mathbf{X}_{\alpha\beta} \\ \mathbf{X}_{\beta\alpha} & \mathbf{X}_{\beta\beta} \\ \mathbf{Y}_{\alpha\alpha} & \mathbf{Y}_{\alpha\beta} \\ \mathbf{Y}_{\beta\alpha} & \mathbf{Y}_{\beta\beta} \end{pmatrix} = \begin{pmatrix} \Omega & 0 & 0 & 0 \\ 0 & \Omega & 0 & 0 \\ 0 & 0 & -\Omega & 0 \\ 0 & 0 & 0 & -\Omega \end{pmatrix} \begin{pmatrix} \mathbf{X}_{\alpha\alpha} & \mathbf{X}_{\alpha\beta} \\ \mathbf{X}_{\beta\alpha} & \mathbf{X}_{\beta\beta} \\ \mathbf{Y}_{\alpha\alpha} & \mathbf{Y}_{\alpha\beta} \\ \mathbf{Y}_{\beta\alpha} & \mathbf{Y}_{\beta\beta} \end{pmatrix} \quad (1.75)$$

Now, there will be $2OV$ unique excitation energies; we sort them into singlets or triplets as follows: for each excitation we compute the overlap between the α and β excitation. For TDA, this is just the ν th column of $\begin{pmatrix} \mathbf{X}_{\alpha\alpha} & \mathbf{X}_{\alpha\beta} \\ \mathbf{X}_{\beta\alpha} & \mathbf{X}_{\beta\beta} \end{pmatrix}$ with the ν th row of $\begin{pmatrix} \mathbf{X}_{\beta\alpha} \\ \mathbf{X}_{\beta\beta} \end{pmatrix}$. If greater than 0, we have a singlet excitation, otherwise we have a triplet excitation. For later use in GW, we just want the neutral excitation energies, so we only care about the singlet excitations.

1.4 Deriving linear response: 11/22

1.4.1 The Fundamentals

The motivation for this is to be able to understand why the poles of the screened Coulomb interaction are the same as those of the fully interacting polarizability, which are given by the frequencies of the RPA, obtained by diagonalizing the Casida equation. And then we want to be able to connect why $W_0 = v + v\chi_0 v + \dots = \frac{v}{1-\chi_0 v}$ where W_0 is the screened Coulomb interaction and χ_0 is the non-interacting polarizability with Lehmann representation.

$$\chi_0(\mathbf{r}, \mathbf{r}', \omega) = \sum_{ia} \frac{\psi_i(\mathbf{r})\psi_a^*(\mathbf{r}')\psi_i(\mathbf{r}')\psi_a^*(\mathbf{r})}{\omega - (\epsilon_a - \epsilon_i) + i\eta \operatorname{sgn}(\epsilon_a - \epsilon_i - \mu)} \quad (1.76)$$

to do so, one must understand the reformulation of based on the density matrix as for posed by Furche [?]. Alternatively, let us start from the known Dyson equation that relates the fully interacting Green's function to the non-interacting one. We know the integral form of the Dyson equation is

$$G(1, 2) = G_0(1, 2) + \int d3d4 G_0(1, 3)\Sigma(3, 4)G(4, 2) \quad (1.77)$$

but we proceed symbolically to get

$$G = G_0 + G_0\Sigma G \quad (1.78)$$

$$(I - G_0\Sigma)G = G_0 \quad (1.79)$$

$$G = (I - G_0\Sigma)^{-1}G_0 \quad (1.80)$$

$$G = (G_0(G_0^{-1} - \Sigma))^{-1}G_0 \quad (1.81)$$

$$G = (G_0^{-1} - \Sigma)^{-1} \quad (1.82)$$

Now, we also know the Dyson equation for the polarizability is

$$\begin{aligned} \chi(\omega, x_1, x_2) = & \chi_0(\omega, x_1, x_2) + \int dx dx' \chi_0(\omega, x_1, x) \\ & \times \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} + f_{xc}(\omega, x, x') \right) \chi(\omega, x', x_2) \end{aligned} \quad (1.83)$$

In the RPA, we neglect the exchange correlation kernel f_{xc} , so we have

$$\chi_{RPA} = \chi_0 + \chi_0 v \chi_{RPA} = \frac{\chi_0}{1 - v \chi_0} \quad (1.84)$$

where in the final step we used the symbolic manipulation that was used before. So $W_0 = \frac{v}{1 - v \chi_0} = v \chi_{RPA} \chi_0^{-1} = v \left(\frac{\chi_0 \chi_0^{-1}}{1 - v \chi_0} \right) = \frac{v}{1 - v \chi_0}$. Therefore, we see why the poles of W_0 are the same as those of χ_{RPA} , since they have a linear relationship. Now, we will proceed to derive the poles of χ_{RPA} . But first we must introduce the density matrix based linear response theory.

1.4.2 Introduction to TDKS

In time-dependent density functional theory (TDDFT), the **Time-Dependent Kohn-Sham (TDKS)** equations describe a system of N noninteracting fermions that reproduce the same time-dependent density $\rho(t, \mathbf{r})$ as the interacting system. The TDKS equations are given by:

$$i \frac{\partial}{\partial t} \varphi_j(t, \mathbf{r}) = H[\rho](t, \mathbf{r}) \varphi_j(t, \mathbf{r}) \quad (1.85)$$

where $j = 1, \dots, N$ indexes the Kohn-Sham orbitals $\varphi_j(t, \mathbf{r})$, and $H[\rho](t, \mathbf{r})$ is the effective one-particle Hamiltonian defined as:

$$H[\rho](t, \mathbf{r}) = \frac{\boldsymbol{\pi}^2(t, \mathbf{r})}{2} + v_{\text{eff}}[\rho](t, \mathbf{r}) \quad (1.86)$$

where $v_{\text{eff}}[\rho](t, \mathbf{r}) = v_{\text{ext}}(t, \mathbf{r}) + v_{\text{H}}[\rho](t, \mathbf{r}) + v_{\text{xc}}[\rho](t, \mathbf{r})$.

The operator $\boldsymbol{\pi}(t, \mathbf{r})$ is known as the **kinetic momentum operator**. In the presence of an electromagnetic field, the kinetic momentum operator is modified from the canonical momentum operator \mathbf{p} to include the effects of the vector potential $\mathbf{A}_{\text{ext}}(t, \mathbf{r})$:

$$\boldsymbol{\pi}(t, \mathbf{r}) = \mathbf{p} + \frac{1}{c} \mathbf{A}_{\text{ext}}(t, \mathbf{r}) \quad (1.87)$$

Here, $\mathbf{p} = -i\hbar\nabla$ is the canonical momentum operator, and c is the speed of light. The vector potential $\mathbf{A}_{\text{ext}}(t, \mathbf{r})$ accounts for the influence of external perturbative electromagnetic fields on the system. *Why it does the influence of the vector potential not just all go into the v_{eff} ?*

But we know that under a gauge transformation, the physical observables will be invariant, while the orbits will merely acquire a **phase factor**:

$$\varphi_j(t, \mathbf{r}) \rightarrow \varphi'_j(t, \mathbf{r}) = \varphi_j(t, \mathbf{r}) \exp\left(-\frac{i}{c}\psi(t, \mathbf{r})\right) \quad (1.88)$$

Therefore observables, like the density or current density will be unaffected by this gauge transformation.

1.4.3 Density Matrix Formulation in TDKS Theory

In Time-Dependent Density Functional Theory (TDDFT), the **Time-Dependent Kohn-Sham (TDKS)** equations 1.85 describe a system of N noninteracting fermions that reproduce the same time-dependent electron density $\rho(t, \mathbf{r})$ as the interacting system. An alternative formulation of TDKS theory utilizes the one-particle density matrix $\gamma(t, \mathbf{r}, \mathbf{r}')$, which offers advantage because it introduces a basis that one can exploit computationally. The one-particle density matrix is defined as:

$$\gamma(t, \mathbf{r}, \mathbf{r}') = \sum_{j=1}^N \varphi_j(t, \mathbf{r}) \varphi_j^*(t, \mathbf{r}') \quad (1.89)$$

and it is idempotent, meaning that

$$\gamma^2(t, \mathbf{r}, \mathbf{r}') = \gamma(t, \mathbf{r}, \mathbf{r}') \quad (1.90)$$

See section ?? for a proof.

Now, we would like to derive an evolution equation for the density matrix in analogy with the one we already have for the KS orbitals in equation 1.85. The result is

$$i \frac{\partial}{\partial t} \gamma(t) = [H[\rho](t), \gamma(t)] \quad (1.91)$$

See section ?? for proof. For the purposes of response theory, it is convenient to consider external scalar potentials,

$$v_{\text{ext}}(t, x) = v^{(0)}(x) + \sum_{\alpha} \lambda_{\alpha} \left(v^{(\alpha)}(\omega_{\alpha}, x) e^{i\omega_{\alpha} t} + v^{(\alpha)}(-\omega_{\alpha}, x) e^{-i\omega_{\alpha} t} \right) \quad (1.92)$$

and longitudinal vector potentials

$$\mathbf{A}_{\text{ext}}(t, x) = \sum_{\alpha} \lambda_{\alpha} \left(\mathbf{A}^{(\alpha)}(\omega_{\alpha}, x) e^{i\omega_{\alpha} t} + \mathbf{A}^{(\alpha)}(-\omega_{\alpha}, x) e^{-i\omega_{\alpha} t} \right) \quad (1.93)$$

Note that we are not considering transverse vector potentials, as we would get if we had a magnetic field. The cemetery of the Fourier component is fate in section ?. Next, we need to determine the derivatives of the observables with respect to a perturbation. We have Any time-dependent expectation value $f_{\lambda}(t)$ is a function of the coupling strength vector $\boldsymbol{\lambda}$. Its response to the external perturbation is defined by its derivatives with respect to $\boldsymbol{\lambda}$ at $\boldsymbol{\lambda} = 0$. For monochromatic perturbations, the derivatives exhibit a characteristic time dependence,

$$f_{\lambda}(t)|_{\boldsymbol{\lambda}=0} = f^{(0)}, \quad (1.94)$$

$$\left. \frac{\partial}{\partial \lambda_{\alpha}} f_{\lambda}(t) \right|_{\boldsymbol{\lambda}=0} = f^{(\alpha)}(\omega_{\alpha}) e^{i\omega_{\alpha} t} + f^{(\alpha)}(-\omega_{\alpha}) e^{-i\omega_{\alpha} t}, \quad (1.95)$$

$$(1.96)$$

Proof of the second expression is given in section ???. The third expression follows by taking the derivative of the second expression.

$$\left. \frac{\partial^2}{\partial \lambda_\alpha \partial \lambda_\beta} f_\lambda(t) \right|_{\lambda=0} = f^{(\alpha\beta)}(\omega_\alpha, \omega_\beta) e^{i(\omega_\alpha + \omega_\beta)t} + f^{(\alpha\beta)}(\omega_\alpha, -\omega_\beta) e^{i(\omega_\alpha - \omega_\beta)t} \quad (1.97)$$

$$+ f^{(\alpha\beta)}(-\omega_\alpha, \omega_\beta) e^{i(-\omega_\alpha + \omega_\beta)t} + f^{(\alpha\beta)}(-\omega_\alpha, -\omega_\beta) e^{-i(\omega_\alpha + \omega_\beta)t} \quad (1.98)$$

These expressions define the frequency dependent response of f_λ up to second order. The key step is to realize that when evaluating the expectation value of some observable O , we must consider the coupling to the density matrix, i.e. $f_\lambda(t) = \text{tr}(O(t)\gamma_\lambda(t))$.

The route to frequency-dependent response properties is then obvious: (1) Calculate the frequencydependent KS density matrix response by differentiation of Eqs. (8) and (10); (2) Take the trace with O . The interacting response can be calculated from the noninteracting KS system because the TDKS density matrix yields the interacting density and current density as it follows from Eq. (9). **Better understanding needed.**

For the idempotency constraint, expansion up to second order yields, in shorthand notation,

$$\gamma^{(0)} = \gamma^{(0)}\gamma^{(0)}, \quad (16)$$

$$\gamma^{(\alpha)} = \gamma^{(0)}\gamma^{(\alpha)} + \gamma^{(\alpha)}\gamma^{(0)}, \quad (17)$$

$$\gamma^{(\alpha\beta)} = \gamma^{(0)}\gamma^{(\alpha\beta)} + \gamma^{(\alpha)}\gamma^{(\beta)} + \gamma^{(\beta)}\gamma^{(\alpha)} + \gamma^{(\alpha\beta)}\gamma^{(0)}. \quad (18)$$

The equations of motion up to second order read

$$0 = [H^{(0)}, \gamma^{(0)}] \quad (1.99)$$

$$\omega_\alpha \gamma^{(\alpha)} = [H^{(0)}, \gamma^{(\alpha)}] + [H^{(\alpha)}, \gamma^{(0)}] \quad (1.100)$$

$$(\omega_\alpha + \omega_\beta) \gamma^{(\alpha\beta)} = [H^{(0)}, \gamma^{(\alpha\beta)}] + [H^{(\alpha)}, \gamma^{(\beta)}] + [H^{(\beta)}, \gamma^{(\alpha)}] + [H^{(\alpha\beta)}, \gamma^{(0)}] \quad (1.101)$$

Proof of this series is given in section ???.

1.5 GW Density Matrix

The expression for the density matrix γ is

$$\gamma(\mathbf{r}, \mathbf{r}') = -\frac{i}{2\pi} \int_{-\infty}^{+\infty} d\omega e^{i\eta\omega} G(\mathbf{r}, \mathbf{r}', \omega) \quad (1.102)$$

Next, we want to consider the expression for the linearized Dyson equation, which is given by

$$G = G_0 + G_0(\Sigma_{xc} - V_{xc})G_0 \quad (1.103)$$

So by inserting this LDE into the expression for the density matrix, we can identify a few different terms. First, consider the term just corresponding to G_0 :

$$\gamma_{\mathbf{k}ij}^{\text{gKS}} = 2\delta_{ij}\theta(\mu - \epsilon_{\mathbf{k}i}) \quad (1.104)$$

We can take a similar approach to treat the static portion of 1.103, i.e., the Hartree-Fock term, which is given by

$$\Delta\gamma_{\mathbf{k}ij}^{\text{HF}} = 2\theta(\mu - \epsilon_{\mathbf{k}i})\theta(\epsilon_{\mathbf{k}j} - \mu) \frac{\langle \mathbf{k}i | \Sigma_x - V_{xc} | \mathbf{k}j \rangle}{\epsilon_{\mathbf{k}i} - \epsilon_{\mathbf{k}j}} \quad (1.105)$$

Note that for a HF noninteracting Green's function, the static term is given by the Hartree-Fock self-energy, but this cancels out exactly with the exchange correlation potential V_{xc} , so this term is zero. Finally we have the most complicated term involving the insertion of $G_0\Sigma_cG_0$. The correlation self energy has a frequency dependence, so what they do is Finally, we get

$$\gamma^{GW} = \gamma^{\text{gKS}} + \Delta\gamma^{\text{HF}} + \Delta\gamma^{GW} \quad (1.106)$$

Chapter 2

Moment-Conserving GW

2.1 Löwdin Downfolding: 2/2/2025

We know that the definition of a Green's function associated with some Hamiltonian \mathbf{H} is given by:

$$(\omega - \mathbf{H}) \mathbf{G} = \mathbf{I} \quad (2.1)$$

where we can consider both cases to be fully interacting. The downfolding tells us to separate into a system \mathcal{S} and auxiliary space \mathcal{L} , so we have:

$$\left(\omega - \begin{pmatrix} \mathbf{H}_{SS} & \mathbf{H}_{S\mathcal{L}} \\ \mathbf{H}_{\mathcal{L}S} & \mathbf{H}_{\mathcal{L}\mathcal{L}} \end{pmatrix} \right) \begin{pmatrix} \mathbf{G}_{SS} & \mathbf{G}_{S\mathcal{L}} \\ \mathbf{G}_{\mathcal{L}S} & \mathbf{G}_{\mathcal{L}\mathcal{L}} \end{pmatrix} = \begin{pmatrix} \mathbf{I}_{SS} & \mathbf{0} \\ \mathbf{0} & \mathbf{I}_{\mathcal{L}\mathcal{L}} \end{pmatrix}.$$

or:

$$\begin{pmatrix} \omega - \mathbf{H}_{SS} & -\mathbf{H}_{S\mathcal{L}} \\ -\mathbf{H}_{\mathcal{L}S} & \omega - \mathbf{H}_{\mathcal{L}\mathcal{L}} \end{pmatrix} \begin{pmatrix} \mathbf{G}_{SS} & \mathbf{G}_{S\mathcal{L}} \\ \mathbf{G}_{\mathcal{L}S} & \mathbf{G}_{\mathcal{L}\mathcal{L}} \end{pmatrix} = \begin{pmatrix} \mathbf{I}_{SS} & \mathbf{0} \\ \mathbf{0} & \mathbf{I}_{\mathcal{L}\mathcal{L}} \end{pmatrix}.$$

Multiplying out the matrices, the \mathcal{S} block gives:

$$(\omega - \mathbf{H}_{SS}) \mathbf{G}_{SS} - \mathbf{H}_{S\mathcal{L}} \mathbf{G}_{\mathcal{L}S} = \mathbf{I}_{SS}. \quad (2.2)$$

Similarly, the \mathcal{L} block gives:

$$-\mathbf{H}_{\mathcal{L}S} \mathbf{G}_{SS} + (\omega - \mathbf{H}_{\mathcal{L}\mathcal{L}}) \mathbf{G}_{\mathcal{L}S} = \mathbf{0}. \quad (2.3)$$

Assuming $(\omega - \mathbf{H}_{\mathcal{L}\mathcal{L}})$ is invertible, from the second equation we obtain:

$$\mathbf{G}_{\mathcal{L}S} = (\omega - \mathbf{H}_{\mathcal{L}\mathcal{L}})^{-1} \mathbf{H}_{\mathcal{L}S} \mathbf{G}_{SS}.$$

Substituting this into the first equation:

$$(\omega - \mathbf{H}_{SS}) \mathbf{G}_{SS} - \mathbf{H}_{S\mathcal{L}} (\omega - \mathbf{H}_{\mathcal{L}\mathcal{L}})^{-1} \mathbf{H}_{\mathcal{L}S} \mathbf{G}_{SS} = \mathbf{I}_{SS}.$$

Factorizing \mathbf{G}_{SS} :

$$[(\omega - \mathbf{H}_{SS}) - \mathbf{H}_{S\mathcal{L}} (\omega - \mathbf{H}_{\mathcal{L}\mathcal{L}})^{-1} \mathbf{H}_{\mathcal{L}S}] \mathbf{G}_{SS} = \mathbf{I}_{SS}.$$

Thus:

$$\mathbf{G}_{SS} = [(\omega - \mathbf{H}_{SS}) - \mathbf{H}_{S\mathcal{L}} (\omega - \mathbf{H}_{\mathcal{L}\mathcal{L}})^{-1} \mathbf{H}_{\mathcal{L}S}]^{-1}.$$

Now, notice that:

$$[\mathbf{G}_{SS}^0(\omega)]^{-1} \equiv \omega - \mathbf{H}_{SS} = \omega - (\mathbf{F} + \mathbf{\Sigma}(\infty)), \implies \mathbf{H}_{SS} = \mathbf{F} + \mathbf{\Sigma}(\infty).$$

where $\mathbf{\Sigma}(\infty)$ is the static self-energy (0 for a HF mean-field reference), and \mathbf{F} is the Fock matrix. Identifying the coupling matrices:

$$\mathbf{H}_{S\mathcal{L}} = \mathbf{W}, \quad \mathbf{H}_{\mathcal{L}S} = \mathbf{W}^\dagger.$$

and

$$\mathbf{H}_{\mathcal{L}\mathcal{L}} = \mathbf{d},$$

Now let us make an ansatz for the upfolded Hamiltonian:

$$\mathbf{H}_{\text{Upfolded}} = \begin{pmatrix} \mathbf{F} + \mathbf{\Sigma}(\infty) & \mathbf{W} \\ \mathbf{W}^\dagger & \mathbf{d} \end{pmatrix}.$$

Then, the resolvent is given by:

$$(\omega - \mathbf{H}_{\text{Upfolded}}) = \begin{pmatrix} \omega - \mathbf{F} - \mathbf{\Sigma}(\infty) & -\mathbf{W} \\ -\mathbf{W}^\dagger & \omega - \mathbf{d} \end{pmatrix} \quad (2.4)$$

Because we are interested in $\mathbf{G}_{SS}(\omega)$, we care about $(\omega - \mathbf{H}_{\text{Upfolded}})^{-1}$ in the upper left block, which is the Schur complement of $(\omega - \mathbf{H}_{\text{Upfolded}})$ with respect to $\omega - \mathbf{d}$, defined as:

$$\mathbf{G}_{SS}(\omega) = \left(\frac{(\omega - \mathbf{H}_{\text{Upfolded}})}{\omega - \mathbf{d}} \right)_{SS}^{-1} = (\omega - (\mathbf{F} + \mathbf{\Sigma}(\infty)) - \mathbf{W} [\omega - \mathbf{d}]^{-1} \mathbf{W}^\dagger)^{-1} \quad (2.5)$$

so the ansatz is correct.

2.2 Cumulant Idea

The definition of the cumulant ansatz for the Green's function is given by:

$$\mathbf{G}_{SS}(t) = \mathbf{G}_{SS}^0(t) e^{\mathbf{C}(t)} \quad (2.6)$$

where $\mathbf{C}(t)$ is the cumulant and $\mathbf{G}_{SS}^0(t)$ is the HF Green's function. By relating the Dyson equation to the Taylor series expansion of the exponential, we can write:

$$\mathbf{G}_{SS}^0(t) \mathbf{C}(t) = \iint dt_1 dt_2 \mathbf{G}_{SS}^0(t - t_1) \mathbf{\Sigma}^c(t_1 - t_2) \mathbf{G}_{SS}^0(t_2) \quad (2.7)$$

Projecting to the spin-orbital basis and inserting the resolution of the identity, we get:

$$\sum_r \langle p | \mathbf{G}_{SS}^0(t) | r \rangle \langle r | \mathbf{C}(t) | q \rangle = \sum_{rs} \iint dt_1 dt_2 \langle p | \mathbf{G}_{SS}^0(t - t_1) | r \rangle \langle r | \Sigma^c(t_1 - t_2) | s \rangle \langle s | \mathbf{G}_{SS}^0(t_2) | q \rangle \quad (2.8)$$

$$\sum_r \mathbf{G}_{pr}^0(t) \mathbf{C}_{rq}(t) = \sum_{rs} \iint dt_1 dt_2 \mathbf{G}_{ps}^0(t - t_1) \Sigma_{sr}^c(t_1 - t_2) \mathbf{G}_{rq}^0(t_2) \quad (2.9)$$

$$\mathbf{G}_{pp}^0(t) \mathbf{C}_{pq}(t) = \underbrace{\iint dt_1 dt_2 \mathbf{G}_{pp}^0(t - t_1) \Sigma_{pq}^c(t_1 - t_2) \mathbf{G}_{qq}^0(t_2)}_{*} \quad (2.10)$$

where $\mathbf{G}_{SS}^0(t) \equiv \mathbf{G}^0(t)$ and in the last step we used the fact that the HF Green's function is diagonal in the spin-orbital basis, specifically $\mathbf{G}_{pp}^0(t) = -i\Theta(t)e^{-i\epsilon_p t}$, where ϵ_p is the HF energy of the p -th spin-orbital. The formula for the inverse Fourier transform is given by:

$$f(t) = \int \frac{d\omega}{2\pi} e^{-i\omega t} f(\omega) \quad (2.11)$$

which implies that

$$\mathbf{G}_{pp}^0(t - t_1) = \int \frac{d\omega}{2\pi} e^{-i\omega(t-t_1)} \mathbf{G}_{pp}^0(\omega) \quad (2.12)$$

$$\Sigma_{pq}^c(t_1 - t_2) = \int \frac{d\omega'}{2\pi} e^{-i\omega'(t_1-t_2)} \Sigma_{pq}^c(\omega') \quad (2.13)$$

$$\mathbf{G}_{qq}^0(t_2) = \int \frac{d\omega''}{2\pi} e^{-i\omega''t_2} \mathbf{G}_{qq}^0(\omega'') \quad (2.14)$$

and plugging into the double time integral $*$, we get:

$$* = \iint dt_1 dt_2 \left[\int \frac{d\omega}{2\pi} e^{-i\omega(t-t_1)} \mathbf{G}_{pp}^0(\omega) \right] \left[\int \frac{d\omega'}{2\pi} e^{-i\omega'(t_1-t_2)} \Sigma_{pq}^c(\omega') \right] \left[\int \frac{d\omega''}{2\pi} e^{-i\omega''t_2} \mathbf{G}_{qq}^0(\omega'') \right] \quad (2.15)$$

$$= \underbrace{\int dt_1 e^{-i(\omega' - \omega)t_1} \int dt_2 e^{-i(\omega'' - \omega')t_2}}_{4\pi^2 \delta(\omega' - \omega) \delta(\omega'' - \omega')} \iiint d\omega d\omega' d\omega'' \frac{e^{-i\omega t}}{8\pi^3} \mathbf{G}_{pp}^0(\omega) \Sigma_{pq}^c(\omega') \mathbf{G}_{qq}^0(\omega'') \quad (2.16)$$

$$= \int \frac{d\omega}{2\pi} e^{-i\omega t} \mathbf{G}_{pp}^0(\omega) \Sigma_{pq}^c(\omega) \mathbf{G}_{qq}^0(\omega) \quad (2.17)$$

But now note that from the left hand side of eqn. 2.10, we can divide out the HF Green's function to get:

$$\mathbf{C}_{pq}(t) = i \int \frac{d\omega}{2\pi} e^{-i(\omega - \epsilon_p)t} \mathbf{G}_{pp}^0(\omega) \Sigma_{pq}^c(\omega) \mathbf{G}_{qq}^0(\omega) \quad (2.18)$$

Now, we insert the unfolded form for the self-energy, which is frequency independent as

$$\Sigma_{pq}^c(\omega) \equiv \Sigma_{pq}^c = \begin{pmatrix} \Sigma(\infty) & \mathbf{W}^< & \mathbf{W}^> \\ \mathbf{W}^{\dagger<} & \mathbf{d}^< & \mathbf{0} \\ \mathbf{W}^{\dagger>} & \mathbf{0} & \mathbf{d}^> \end{pmatrix}_{pq}. \text{ Customarily this is the point where the diagonal}$$

approximation for the self-energy is introduced instead. We also know that $\mathbf{G}_{pp}^0(\omega) = \frac{\mathbf{I}}{\omega - \epsilon_p}$. We can then write:

$$\mathbf{C}_{pq}(t) = i\mathbf{\Sigma}_{pq}^c \int \frac{d\omega}{2\pi} \frac{e^{-i(\omega - \epsilon_p)t}}{(\omega - \epsilon_p)(\omega - \epsilon_q)} \quad (2.19)$$

$$= i \frac{\mathbf{\Sigma}_{pq}^c}{\epsilon_q - \epsilon_p} \left[\underbrace{\int \frac{d\omega}{2\pi} \frac{e^{-i(\omega - \epsilon_p)t}}{\omega - \epsilon_p}}_{-i\Theta(t)} - \underbrace{\int \frac{d\omega}{2\pi} \frac{e^{-i(\omega - \epsilon_q)t}}{\omega - \epsilon_q}}_{e^{-i(\epsilon_q - \epsilon_p)t}(-i\Theta(t))} \right] \quad (2.20)$$

$$= \frac{\mathbf{\Sigma}_{pq}^c}{\epsilon_q - \epsilon_p} \Theta(t) [1 - e^{-i(\epsilon_q - \epsilon_p)t}] \quad (2.21)$$

$$(2.22)$$

So now we insert this expression into our original ansatz for the cumulant, and we get:

$$G(t) = G^0(t) e^{\frac{\mathbf{\Sigma}_{pq}^c}{\epsilon_q - \epsilon_p} \Theta(t) [1 - e^{-i(\epsilon_q - \epsilon_p)t}]} \quad (2.23)$$

2.3 Lanczos Iteration

The block tridiagonal form can be expressed as:

$$\tilde{\mathbf{H}}_{\text{tri}} = \tilde{\mathbf{q}}^{(j)\dagger} \begin{bmatrix} \mathbf{f} + \mathbf{\Sigma}_\infty & \mathbf{W} \\ \mathbf{W}^\dagger & \mathbf{d} \end{bmatrix} \tilde{\mathbf{q}}^{(j)} \quad (2.24)$$

$$= \begin{bmatrix} \mathbf{f} + \mathbf{\Sigma}_\infty & \mathbf{L} & & & \mathbf{0} \\ \mathbf{L}^\dagger & \mathbf{H}_1 & \mathbf{C}_1 & & \\ & \mathbf{C}_1^\dagger & \mathbf{H}_2 & \mathbf{C}_2 & \\ & & \mathbf{C}_2^\dagger & \mathbf{H}_3 & \ddots \\ & & & \ddots & \ddots & \mathbf{C}_{j-1} \\ \mathbf{0} & & & & \mathbf{C}_{j-1}^\dagger & \mathbf{H}_j \end{bmatrix} \quad (2.25)$$

where we define $\tilde{\mathbf{q}}^{(j)}$ as

$$\tilde{\mathbf{q}}^{(j)} = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{q}^{(j)} \end{bmatrix} \quad (2.26)$$

This formulation becomes exact when the level j equals N , the dimension of the original hamiltonian; this corresponds to considering up to the highest moment of the self-energy, i.e. n france from $1, \dots, N$. in practice, however, we always truncate the Krylov subspace to some $j < N$. Note that the tridiagonal form never actually forces us to compute \mathbf{W} or \mathbf{d} , as desired.

2.3.1 Creation of Krylov Subspace

Formally, the Krylov subspace of level j is given as $\mathbf{q}^{(j)} = [\mathbf{q}_1, \mathbf{q}_2, \dots, \mathbf{q}_j]$, where the projection of the full Hamiltonian onto this subspace gives the tridiagonal form of equation 2.25. To start building up the subspace, we need to determine \mathbf{q}_1 via QR decomposition of the exact GW couplings as $\mathbf{W}^\dagger = \mathbf{q}_1 \mathbf{L}^\dagger \rightarrow \mathbf{q}_1 = \mathbf{W}^\dagger \mathbf{L}^{\dagger, -1}$. \mathbf{L} is defined in terms of just the 0th order self-energy moment as $\mathbf{L}^\dagger = (\Sigma^{(0)})^{\frac{1}{2}}$. We build up the subsequent q_i vectors through a three-term recurrence

$$\mathbf{q}_{i+1} \mathbf{C}_i^\dagger = [\mathbf{d} \mathbf{q}_i - \mathbf{q}_i \mathbf{H}_i - \mathbf{q}_{i-1} \mathbf{C}_{i-1}], \quad (2.27)$$

where the on-diagonal blocks are defined as

$$\mathbf{H}_i = \mathbf{q}_i^\dagger \mathbf{d} \mathbf{q}_i \quad (2.28)$$

Notice that to form the initial vector \mathbf{q}_1 we would need \mathbf{W}^\dagger and to continue building the subspace, we would need \mathbf{d} , so to avoid this, we introduce the self-energy moments.

2.3.2 A sketch of the implicit Lanczos method

Due to Garnet's paper on the quasi-boson G_0W_0 method, we know that we have a form for an upfolded G_0W_0 Hamiltonian as

$$\mathbf{H}_{\text{Upfolded}}^{G_0W_0} = \begin{pmatrix} \mathbf{F} + \Sigma(\infty) & \mathbf{W}^< & \mathbf{W}^> \\ \mathbf{W}^{<, \dagger} & \mathbf{d}^< & 0 \\ \mathbf{W}^{>, \dagger} & 0 & \mathbf{d}^> \end{pmatrix} \quad (2.29)$$

with quantities defined separately for lesser and greater parts. But we will just focus on the lesser part for now, where matrix elements of the screened interaction $\mathbf{W}^<$ are given by

$$W_{pkv}^< = \sum_{ia} (pk|ia) (X_{ia}^v + Y_{ia}^v) \quad (2.30)$$

and

$$d_{kv,lv'}^< = (\epsilon_k - \Omega_v) \delta_{k,l} \delta_{v,v'} \quad (2.31)$$

Note that we get the factor of $\sqrt{2}$ accompanying all ERIs in RHF because we are considering the expectation value of the form

$$\frac{1}{2} \sum_{pqrs} \langle pq||rs \rangle \langle \Psi_0 | \left(\hat{T}_i^{a,\alpha} + \hat{T}_i^{a,\beta} \right)^\dagger \left(a_p^\dagger a_q^\dagger a_s a_r \left(\hat{T}_i^{a,\alpha} + \hat{T}_i^{a,\beta} \right) \right) | \Psi_0 \rangle \quad (2.32)$$

where we have the excitation operator for a given spin channel as $\hat{T}_i^{a,\sigma} = a_a^{\dagger,\sigma} a_i^\sigma$ and a singlet state for the RHF ground state carrying a factor of $\frac{1}{\sqrt{2}}$. If we apply Wick's theorem to this string, we get a contribution from both the α and β channels, so $\frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}} = \sqrt{2}$.

Through the introduction of a Krylov subspace as

$$\tilde{\mathbf{H}}_{\text{Upfolded}}^{G_0W_0} = \tilde{\mathbf{Q}}^{(n,\dagger)} \mathbf{H}_{\text{Upfolded}}^{G_0W_0} \tilde{\mathbf{Q}}^{(n)} \quad (2.33)$$

where $\mathbf{Q}^{(n)} \equiv (\mathbf{q}_1 \ \mathbf{q}_2 \ \cdots \ \mathbf{q}_n)$ is the block Krylov subspace spanned by the Lanczos vectors, but we want to preserve the physical space of $\mathbf{F} + \Sigma(\infty)$ so we are really interested in the projection matrix

$$\tilde{\mathbf{Q}}^{(n)} = \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}^{(n)} \end{pmatrix} \quad (2.34)$$

To get a gist of what the block Lanczos will do, let's just consider the case where we have two Lanczos vectors, so that we have a projection matrix of the form

$$\tilde{\mathbf{Q}}^{(2)} = \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}^{(2)} \end{pmatrix} \quad (2.35)$$

So

$$\tilde{\mathbf{H}}_{\text{upfolded}}^{\text{Lanczos Iter 2}} = \tilde{\mathbf{Q}}^{(2,\dagger)} \mathbf{H}_{\text{Upfolded}}^{G_0 W_0} \tilde{\mathbf{Q}}^{(2)} \quad (2.36)$$

$$= \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}^{(2)\dagger} \end{pmatrix} \begin{pmatrix} \mathbf{F} + \Sigma(\infty) & \mathbf{W} \\ \mathbf{W}^\dagger & d \end{pmatrix} \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}^{(2)} \end{pmatrix} \quad (2.37)$$

$$= \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & [\mathbf{q}_1^\dagger \ \mathbf{q}_2^\dagger] \end{pmatrix} \begin{pmatrix} \mathbf{F} + \Sigma(\infty) & \mathbf{W} \\ \mathbf{W}^\dagger & d \end{pmatrix} \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & [\mathbf{q}_1 \ \mathbf{q}_2] \end{pmatrix} \quad (2.38)$$

$$= \begin{pmatrix} \mathbf{F} + \Sigma(\infty) & \mathbf{W} \\ [\mathbf{q}_1^\dagger \ \mathbf{q}_2^\dagger] \mathbf{W}^\dagger & [\mathbf{q}_1^\dagger \ \mathbf{q}_2^\dagger] d \end{pmatrix} \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & [\mathbf{q}_1 \ \mathbf{q}_2] \end{pmatrix} \quad (2.39)$$

$$= \begin{pmatrix} \mathbf{F} + \Sigma(\infty) & \begin{bmatrix} \underbrace{\mathbf{W} \mathbf{q}_1}_{\mathcal{R} \mathcal{Q}^\dagger \mathcal{Q} = \mathcal{R}} & \underbrace{\mathbf{W} \mathbf{q}_2}_{\mathbf{0}} \end{bmatrix} \\ \begin{bmatrix} \underbrace{\mathbf{q}_1^\dagger \mathbf{W}^\dagger}_{\mathcal{Q}^\dagger \mathcal{Q} \mathcal{R}^\dagger = \mathcal{R}^\dagger} & \underbrace{\mathbf{q}_2^\dagger \mathbf{W}^\dagger}_{\mathbf{0}} \end{bmatrix} & \begin{pmatrix} \underbrace{\mathbf{q}_1^\dagger d \mathbf{q}_1}_{M_1} & \underbrace{\mathbf{q}_1^\dagger d \mathbf{q}_2}_{C_1} \\ \underbrace{\mathbf{q}_2^\dagger d \mathbf{q}_1}_{C_1^\dagger} & \underbrace{\mathbf{q}_2^\dagger d \mathbf{q}_2}_{M_2} \end{pmatrix} \end{pmatrix} \quad (2.40)$$

where in the last line we used the fact that we are free to choose our $\mathbf{q}_1 \equiv \mathcal{Q}$ as the same orthogonal matrix employed in constructing the QR decomposition of \mathbf{W}^\dagger as

$$\mathbf{W}^\dagger = \mathcal{Q} \mathcal{R}^\dagger \implies \mathbf{q}_1 = \mathbf{W}^\dagger \mathcal{R}^{-1, \dagger} \quad (2.41)$$

2.3.3 Physical-auxiliary coupling W

Now consider $\mathbf{W} \mathbf{W}^\dagger = \mathcal{R} \mathcal{Q} \mathcal{Q}^\dagger \mathcal{R}^\dagger = \mathcal{R} \mathcal{R}^\dagger$. So if we can do a Cholesky decomposition of $\mathbf{W} \mathbf{W}^\dagger$ we would get access to \mathcal{R} . But consider that

$$\Sigma_{pq}^{(n, <)} = \sum_{ia, jb, k} \sum_{\mu} (pk|ia) (X_{ia}^\mu + Y_{ia}^\mu) (X_{jb}^\mu + Y_{jb}^\mu) (qk|jb) [(\epsilon_k - \Omega_\mu)]^n \quad (2.42)$$

so it becomes clear that $\mathbf{W} \mathbf{W}^\dagger = \Sigma^0 \implies \mathcal{R} = (\mathbf{W} \mathbf{W}^\dagger)^{1/2} = (\Sigma^0)^{1/2}$, which we hope to be able to accomplish with the Cholesky decomposition.

2.3.4 Auxiliary-auxiliary space d: the working equations

From above, notice that

$$\mathbf{M}_i = \mathbf{q}_i^\dagger \mathbf{d} \mathbf{q}_i \quad \text{and} \quad \mathbf{C}_i = \mathbf{q}_i^\dagger \mathbf{d} \mathbf{q}_{i+1} \quad (2.43)$$

To get these, define

$$\mathbf{S}_{i,j}^{(n)} = \mathbf{q}_i^\dagger \mathbf{d}^n \mathbf{q}_j \quad (2.44)$$

So it must be that $\mathbf{S}_{0,j}^{(n)} = \mathbf{S}_{i,0}^{(n)} = 0$ for all i, j , $\mathbf{S}_{i,j}^{(0)} = \delta_{ij} \mathbf{I}$, and we can demand Hermiticity, so that $\mathbf{S}_{i,j}^{(n)} = \mathbf{S}_{j,i}^{(n)\dagger}$. We are able to initialize \mathbf{S} using

$$\mathbf{S}_{1,1}^{(n)} = \mathbf{q}_1^\dagger \mathbf{d}^n \mathbf{q}_1 = \mathbf{R}^{-1} \mathbf{W} \mathbf{d}^n \mathbf{W}^\dagger \mathbf{R}^{-1,\dagger} = \mathbf{R}^{-1} \boldsymbol{\Sigma}^{(n)} \mathbf{R}^{-1,\dagger} \quad (2.45)$$

So looking at eqn. 2.117, we see that the on-diagonal elements are $\mathbf{M}_i = \mathbf{S}_{i,i}^{(1)}$ while the off-diagonal elements are $\mathbf{C}_i = \mathbf{S}_{i,i+1}^{(1)}$. The familiar three-term Lanczos recurrence is

$$\mathbf{q}_{i+1} \mathbf{C}_i^\dagger = [\mathbf{d} \mathbf{q}_i - \mathbf{q}_i \mathbf{M}_i - \mathbf{q}_{i-1} \mathbf{C}_{i-1}] \implies \mathbf{q}_{i+1} = [\mathbf{d} \mathbf{q}_i - \mathbf{q}_i \mathbf{M}_i - \mathbf{q}_{i-1} \mathbf{C}_{i-1}] \mathbf{C}_i^{\dagger,-1} \quad (2.46)$$

where the participants are block vectors and we have assumed that \mathbf{C}_i is invertible. Let us start by considering the form of

$$\mathbf{S}_{i+1,i}^n \equiv \mathbf{q}_{i+1}^\dagger \mathbf{d}^n \mathbf{q}_i = \left[[\mathbf{d} \mathbf{q}_i - \mathbf{q}_i \mathbf{M}_i - \mathbf{q}_{i-1} \mathbf{C}_{i-1}] \mathbf{C}_i^{\dagger,-1} \right]^\dagger \mathbf{d}^n \mathbf{q}_i \quad (2.47)$$

$$= \mathbf{C}_i^{-1} \left[\underbrace{\mathbf{q}_i^\dagger \mathbf{d}^{n+1} \mathbf{q}_i}_{\mathbf{S}_{i,i}^{n+1}} - \mathbf{M}_i \underbrace{\mathbf{q}_i^\dagger \mathbf{d}^n \mathbf{q}_i}_{\mathbf{S}_{i,i}^n} - \mathbf{C}_{i-1}^\dagger \underbrace{\mathbf{q}_{i-1}^\dagger \mathbf{d}^n \mathbf{q}_i}_{\mathbf{S}_{i-1,i}^n} \right] \quad (2.48)$$

$$= \boxed{\mathbf{C}_i^{-1} \left[\mathbf{S}_{i,i}^{n+1} - \mathbf{M}_i \mathbf{S}_{i,i}^n - \mathbf{C}_{i-1}^\dagger \mathbf{S}_{i-1,i}^n \right]} \quad (2.49)$$

Similarly

$$\mathbf{S}_{i+1,i+1}^n \equiv \mathbf{q}_{i+1}^\dagger \mathbf{d}^n \mathbf{q}_{i+1} = \left[[\mathbf{d} \mathbf{q}_i - \mathbf{q}_i \mathbf{M}_i - \mathbf{q}_{i-1} \mathbf{C}_{i-1}] \mathbf{C}_i^{\dagger,-1} \right]^\dagger \mathbf{d}^n [\mathbf{d} \mathbf{q}_i - \mathbf{q}_i \mathbf{M}_i - \mathbf{q}_{i-1} \mathbf{C}_{i-1}] \mathbf{C}_i^{\dagger,-1} \quad (2.50)$$

$$(2.51)$$

$$\begin{aligned}
S_{i+1,i+1}^n &= C_i^{-1} \left[S_{i,i}^{n+2} + M_i S_{i,i}^n M_i + C_{i-1}^\dagger S_{i-1,i-1}^n C_{i-1} \right. \\
&\quad - \underbrace{q_i^\dagger d^{n+1} q_i}_{S_{i,i}^{n+1}} M_i - M_i \underbrace{q_i^\dagger d^{n+1} q_i}_{S_{i,i}^{n+1}} \\
&\quad - \underbrace{q_i^\dagger d^{n+1} q_{i-1}}_{S_{i,i-1}^{n+1}} C_{i-1} - C_{i-1}^\dagger \underbrace{q_{i-1}^\dagger d^{n+1} q_i}_{S_{i-1,i}^{n+1}} \\
&\quad \left. + M_i \underbrace{q_i^\dagger d^n q_{i-1}}_{S_{i,i-1}^n} C_{i-1} + C_{i-1}^\dagger \underbrace{q_{i-1}^\dagger d^n q_i}_{S_{i-1,i}^n} M_i \right] C_i^{\dagger,-1} \quad (2.52)
\end{aligned}$$

$$\begin{aligned}
&= C_i^{-1} \left[S_{i,i}^{n+2} + M_i S_{i,i}^n M_i + C_{i-1}^\dagger S_{i-1,i-1}^n C_{i-1} \right. \\
&\quad \left. - P(S_{i,i}^{n+1} M_i) - P(S_{i,i-1}^{n+1} C_{i-1}) + P(M_i S_{i,i-1}^n C_{i-1}) \right] C_i^{\dagger,-1} \quad (2.53)
\end{aligned}$$

where we introduced the permutation operator as $P(A) = A + A^\dagger$. Setting $n = 0$ we get

$$I = C_i^{-1} \left[S_{i,i}^2 + M_i^2 + C_{i-1}^\dagger C_{i-1} - P(M_i^2) - P(S_{i,i-1}^1 C_{i-1}) + 0 \right] C_i^{\dagger,-1} \quad (2.54)$$

$$\Rightarrow C_i^2 = C_i C_i^\dagger = \boxed{S_{i,i}^2 + M_i^2 + C_{i-1}^\dagger C_{i-1} - P(S_{i,i}^1 M_i) - P(S_{i,i-1}^1 C_{i-1})} \quad (2.55)$$

$$\Rightarrow C_i C_i^\dagger \equiv q_i^\dagger d q_{i+1} q_{i+1}^\dagger d q_i = q_i^\dagger d^2 q_i \quad (2.56)$$

The hope is that we can use the Cholesky QR algorithm to take the effective matrix square root to get the C_i .

2.4 Efficient generation of the self-energy moments

Since the self-energy is defined as a convolution between the interacting Green's function and the screened Coulomb potential in GW we can use the known formula for the moment distribution of a convolution of two quantities to get

$$\Sigma_{pq}^{(n,<)} = \sum_{ia,jb,k} \sum_{t=0}^n \binom{n}{t} (-1)^t \epsilon_k^{n-t} (pk \mid ia) \eta_{ia,jb}^{(t)} (qk \mid jb), \quad (2.57)$$

where we have defined the density-density response moment as

$$\eta_{ia,jb}^{(n)} = \sum_v (X_{ia}^v + Y_{ia}^v) \Omega_v^n (X_{jb}^v + Y_{jb}^v) \quad (2.58)$$

2.4.1 An alternative formulation of the RPA polarizability with the density response moments

The Casida equation is given by

$$\begin{pmatrix} A & B \\ -B & -A \end{pmatrix} \begin{pmatrix} X & Y \\ Y & X \end{pmatrix} \begin{pmatrix} \Omega & 0 \\ 0 & -\Omega \end{pmatrix} = \begin{pmatrix} X & Y \\ Y & X \end{pmatrix} \quad (2.59)$$

where the excitation \mathbf{X} and de-excitation \mathbf{Y} eigenvectors form the biorthogonal set as

$$(\mathbf{X} + \mathbf{Y})(\mathbf{X} - \mathbf{Y})^T = (\mathbf{X} + \mathbf{Y})^T(\mathbf{X} - \mathbf{Y}) = \mathbf{I} \quad (2.60)$$

The \mathbf{A} and \mathbf{B} matrices are defined as

$$A_{ia,jb} = (\epsilon_a - \epsilon_i) \delta_{ij} \delta_{ab} + \mathcal{K}_{ia,bj} \quad (2.61)$$

$$B_{ia,jb} = \mathcal{K}_{ia,jb} \quad (2.62)$$

and I take the direct approximation, so $\mathcal{K}_{ia,jb} = (ia | jb) = \mathcal{K}_{ia,bj}$. As I showed earlier this year, these neutral excitation energies Ω define the poles of the polarizability $\chi_{\text{RPA}}(\omega)$ as

$$\chi_{\text{RPA}}(\omega) = \begin{bmatrix} \mathbf{X} & \mathbf{Y} \\ \mathbf{Y} & \mathbf{X} \end{bmatrix} \begin{bmatrix} \omega \mathbf{I} - \Omega & \mathbf{0} \\ \mathbf{0} & -\omega \mathbf{I} - \Omega \end{bmatrix}^{-1} \begin{bmatrix} \mathbf{X} & \mathbf{Y} \\ \mathbf{Y} & \mathbf{X} \end{bmatrix}^T. \quad (2.63)$$

where $\chi_{\text{RPA}}(\omega) = (\chi_0(\omega)^{-1} - \mathcal{K})^{-1}$, where $\chi_0(\omega)$ is the irreducible polarizability of the reference state. Because of the bosonic-like symmetry in equation 2.63, we can write a more compact form of the RPA polarizability as

$$\eta(\omega) = (\mathbf{X} + \mathbf{Y})(\omega \mathbf{I} - \Omega)^{-1}(\mathbf{X} + \mathbf{Y})^T. \quad (2.64)$$

However, here we are interested in the spectral moments of the compactified RPA polarizability in equation 2.64 over all RPA excitation energies, which is given as

$$\eta_{ia,jb}^{(n)} = -\frac{1}{\pi} \int_0^\infty \text{Im} [\eta_{ia,jb}(\omega)] \omega^n d\omega = -\frac{1}{\pi} (\mathbf{X} + \mathbf{Y}) \left[\int_0^\infty \text{Im} [(\omega \mathbf{I} - \Omega)^{-1}] \omega^n d\omega \right] (\mathbf{X} + \mathbf{Y})^T. \quad (2.65)$$

where in the final equality we have just factored out the frequency independent piece. Now, we can use the identity from complex analysis that $\frac{1}{-\Omega + \mathbf{I}(\omega + i\eta)} = P \left(\frac{1}{\omega \mathbf{I} - \Omega} \right) - i\pi \delta(\omega - \Omega) \implies \text{Im} \left[\frac{1}{-\Omega + \mathbf{I}(\omega + i\eta)} \right] = -\pi \delta(\omega - \Omega)$, where P is the Cauchy principal value, so

$$\int_0^\infty \text{Im} [(\omega \mathbf{I} - \Omega)^{-1}] \omega^n d\omega = -\pi \int_0^\infty \delta(\omega - \Omega) \omega^n d\omega = -\pi \Omega^n. \quad (2.66)$$

and plugging back and, we get $\boldsymbol{\eta}^{(n)} = (\mathbf{X} + \mathbf{Y}) (\Omega^n) (\mathbf{X} + \mathbf{Y})^T$.

2.4.2 Getting η with lower scaling

Now we will make use of the symmetric formulation of the RPA problem by Phillip Furche. The RPA eigenvalue problem is given by

$$\begin{pmatrix} \mathbf{A} & \mathbf{B} \\ -\mathbf{B} & -\mathbf{A} \end{pmatrix} \begin{pmatrix} \mathbf{X} \\ \mathbf{Y} \end{pmatrix} = \Omega \begin{pmatrix} \mathbf{X} \\ \mathbf{Y} \end{pmatrix} \quad (2.67)$$

so we can get the coupled equations

$$\mathbf{A}\mathbf{X} + \mathbf{B}\mathbf{Y} = \Omega \mathbf{X} \quad (2.68)$$

$$-\mathbf{B}\mathbf{X} - \mathbf{A}\mathbf{Y} = \Omega \mathbf{Y} \quad (2.69)$$

Adding and subtracting these two equations, we get

$$(\mathbf{A} - \mathbf{B})(\mathbf{X} - \mathbf{Y}) = (\mathbf{X} + \mathbf{Y})\mathbf{\Omega} \implies (\mathbf{A} - \mathbf{B}) = (\mathbf{X} + \mathbf{Y})\mathbf{\Omega}(\mathbf{X} - \mathbf{Y})^\dagger \implies \boxed{\boldsymbol{\eta}^{(1)} = \mathbf{A} - \mathbf{B}} \quad (2.70)$$

$$(\mathbf{A} + \mathbf{B})(\mathbf{X} + \mathbf{Y}) = (\mathbf{X} - \mathbf{Y})\mathbf{\Omega} \implies (\mathbf{A} + \mathbf{B}) = (\mathbf{X} - \mathbf{Y})\mathbf{\Omega}(\mathbf{X} + \mathbf{Y})^\dagger \quad (2.71)$$

But then also notice that since $\boldsymbol{\eta}^{(0)} = (\mathbf{X} + \mathbf{Y})(\mathbf{X} + \mathbf{Y})^\dagger$, we can write $\boldsymbol{\eta}^{(1)} = \boldsymbol{\eta}^{(0)}(\mathbf{A} + \mathbf{B})\boldsymbol{\eta}^{(0)}$. Continuing on, we arrive at Furche's symmetric formulation of the RPA problem as

$$(\mathbf{A} - \mathbf{B})(\mathbf{A} + \mathbf{B})(\mathbf{X} + \mathbf{Y}) = (\mathbf{X} + \mathbf{Y})\mathbf{\Omega}^2 \quad (2.72)$$

By right multiplying by $(\mathbf{X} + \mathbf{Y})^\dagger$, this leads to

$$(\mathbf{A} - \mathbf{B})(\mathbf{A} + \mathbf{B})\boldsymbol{\eta}^{(0)} = \boldsymbol{\eta}^{(2)} \quad (2.73)$$

This is suggestive of a recursive relation with the form

$$\boldsymbol{\eta}^{(m)} = (\mathbf{A} - \mathbf{B})(\mathbf{A} + \mathbf{B})\boldsymbol{\eta}^{(m-2)} \quad (2.74)$$

$$(2.75)$$

But we have already found that $\boldsymbol{\eta}^{(1)} = \mathbf{A} - \mathbf{B} \implies \boldsymbol{\eta}^{(2)} = \boldsymbol{\eta}^{(1)}(\mathbf{A} + \mathbf{B})\boldsymbol{\eta}^{(0)}$. Now plug in $\boldsymbol{\eta}^{(1)} = \boldsymbol{\eta}^{(0)}(\mathbf{A} + \mathbf{B})\boldsymbol{\eta}^{(0)}$ to get

$$\boldsymbol{\eta}^{(2)} = \boldsymbol{\eta}^{(0)}(\mathbf{A} + \mathbf{B})\boldsymbol{\eta}^{(0)}(\mathbf{A} + \mathbf{B})\boldsymbol{\eta}^{(0)} = [\boldsymbol{\eta}^{(0)}(\mathbf{A} + \mathbf{B})]^2 \boldsymbol{\eta}^{(0)} \quad (2.76)$$

Repeating gives

$$\boxed{\boldsymbol{\eta}^{(m)} = [\boldsymbol{\eta}^{(0)}(\mathbf{A} + \mathbf{B})]^m \boldsymbol{\eta}^{(0)}} \quad (2.77)$$

and then to initialize, consider

$$\mathbf{A} - \mathbf{B} = \boldsymbol{\eta}^{(0)}(\mathbf{A} + \mathbf{B})\boldsymbol{\eta}^{(0)} \quad (2.78)$$

$$(\mathbf{A} - \mathbf{B})(\mathbf{A} + \mathbf{B}) = \boldsymbol{\eta}^{(0)}(\mathbf{A} + \mathbf{B})\boldsymbol{\eta}^{(0)}(\mathbf{A} + \mathbf{B}) = [\boldsymbol{\eta}^{(0)}(\mathbf{A} + \mathbf{B})]^2 \quad (2.79)$$

$$\implies \boldsymbol{\eta}^{(0)} = [(\mathbf{A} - \mathbf{B})(\mathbf{A} + \mathbf{B})]^{1/2}(\mathbf{A} + \mathbf{B})^{-1} \quad (2.80)$$

We do assume a lot of things in going to equation 2.80, but I have

```
1 assert np.all(np.linalg.eigvals(ApB) > 0)
```

2.4.3 Bringing it back to outline an efficient procedure for Computing Self-Energy Moments

The moments of the lesser and greater parts of the self-energy have the form

$$\begin{aligned} \Sigma_{pq}^{(n,<)} &= \sum_{ia,jb,k} \sum_{t=0}^n \binom{n}{t} (-1)^t \epsilon_k^{n-t} (pk | ia) \eta_{ia,jb}^{(t)} (qk | jb), \\ \Sigma_{pq}^{(n,>)} &= \sum_{ia,jb,c} \sum_{t=0}^n \binom{n}{t} \epsilon_c^{n-t} (pc | ia) \eta_{ia,jb}^{(t)} (qc | jb), \end{aligned} \quad (2.81)$$

respectively. The energies ϵ and integrals $(pq | rs)$ are known to us from the prior mean-field calculation, but the density-density moments $\eta^{(t)}$ are not, so we need to compute them. We find them to be defined as

$$\boldsymbol{\eta}^{(m)} = [\boldsymbol{\eta}^{(0)}(\mathbf{A} + \mathbf{B})]^m \boldsymbol{\eta}^{(0)}, \quad (2.82)$$

with the initial

$$\boldsymbol{\eta}^{(0)} = [(\mathbf{A} - \mathbf{B})(\mathbf{A} + \mathbf{B})]^{\frac{1}{2}}(\mathbf{A} + \mathbf{B})^{-1} \quad (2.83)$$

where we have \mathbf{A} and \mathbf{B} with components $A_{ia,jb} = \delta_{ij}\delta_{ab}(\epsilon_a - \epsilon_i) + (ia | jb)$ and $B_{ia,jb} = (ia | jb)$. Note that the scaling of the above would be improved by introducing low-rank approximations to the electron repulsion integrals (ERIs) via the Cholesky decomposition or tensor hyper-contraction, which express these 4-index quantities as a sum of two 3- or five 2-index tensors, respectively.

2.5 Avoiding auxiliary space

To avoid using the large auxiliary quantities, we introduce an operator which will project onto the block Lanczos space as $\mathbf{S}_{i,j}^{(n)} = \mathbf{q}_i^\dagger \mathbf{d}^n \mathbf{q}_j$. But due to the orthogonality of the Krylov subspace, we have $q_i^\dagger q_j = 0$ for $i \neq j$, so $\mathbf{S}_{i,j}^{(n)} = 0$ for $|i - j| > 1$. Furthermore, due to Hermiticity, $\mathbf{S}_{i,j}^{(n)} = \mathbf{S}_{j,i}^{(n)\dagger}$. We can start with the initial definition $\mathbf{S}_{1,1}^{(n)} = \mathbf{q}_1^\dagger \mathbf{d}^n \mathbf{q}_1 = \mathbf{L}^{-1} \boldsymbol{\Sigma}^{(n)} \mathbf{L}^{-1,\dagger}$.

Then we know that the recurrence relation is given by

$$\mathbf{q}_{i+1} \mathbf{C}_i^\dagger = [\mathbf{d} \mathbf{q}_i - \mathbf{q}_i \mathbf{H}_i - \mathbf{q}_{i-1} \mathbf{C}_{i-1}] \quad (2.84)$$

I will not repeat the algebraic manipulations, but Backhouse shows in his thesis that the following relations follow

$$\begin{aligned} \mathbf{S}_{i+1,i}^{(n)} &= \mathbf{q}_{i+1}^\dagger \mathbf{d}^n \mathbf{q}_i = \mathbf{C}_i^{-1} \left[\mathbf{S}_{i,i}^{(n+1)} - \mathbf{H}_i \mathbf{S}_{i,i}^{(n)} - \mathbf{C}_{i-1}^\dagger \mathbf{S}_{i-1,i}^{(n)} \right] \\ \mathbf{S}_{i+1,i+1}^{(n)} &= \mathbf{q}_{i+1}^\dagger \mathbf{d}^n \mathbf{q}_{i+1} = \mathbf{C}_i^{-1} \left[\mathbf{S}_{i,i}^{(n+2)} + \mathbf{H}_i \mathbf{S}_{i,i}^{(n)} \mathbf{H}_i + \mathbf{C}_{i-1}^\dagger \mathbf{S}_{i-1,i-1}^{(n)} \mathbf{C}_{i-1} \right. \\ &\quad \left. - P \left(\mathbf{S}_{i,i}^{(n+1)} \mathbf{H}_i \right) + P \left(\mathbf{H}_i \mathbf{S}_{i,i-1}^{(n)} \mathbf{C}_{i-1} \right) - P \left(\mathbf{S}_{i,i-1}^{(n+1)} \mathbf{C}_{i-1} \right) \right] \mathbf{C}_i^{-1,\dagger}, \end{aligned} \quad (2.85)$$

and then solving for \mathbf{C}_i^2

$$\mathbf{C}_i^2 = \left[\mathbf{S}_{i,i}^{(2)} + \mathbf{H}_i^2 + \mathbf{C}_{i-1}^\dagger \mathbf{C}_{i-1} - P \left(\mathbf{S}_{i,i}^{(1)} \mathbf{H}_i \right) - P \left(\mathbf{S}_{i,i-1}^{(1)} \mathbf{C}_{i-1} \right) \right] \quad (2.86)$$

and we can also find the on-diagonal \mathbf{H} matrices using

$$\mathbf{H}_i = \mathbf{q}_i^\dagger \mathbf{d} \mathbf{q}_i = \mathbf{S}_{i,i}^{(1)}. \quad (2.87)$$

Now, we know how to compute every quantity of equation 2.25.

2.6 Spectral Function

When we diagonalize the unfolded Hamiltonian, the eigenpairs are composed of charged excitation energies E_k (analogous to QP energies from the QP equation, but without a diagonal approximation to the self-energy) and eigenvectors \mathbf{u}_k , which can be transformed into the Dyson orbitals $\boldsymbol{\psi}_k$ via

$$\boldsymbol{\psi}_k = \mathbf{L} \mathbf{P} \mathbf{u}_k \quad (2.88)$$

where \mathbf{P} is the projection operator into the physical space

```
1 eigvec_phys = extracted_eigvecs[j][:mf.nbsf]
```

and then \mathbf{L} , depending on whether we have an occupied or virtual state, is

```
1 moments_less = [form_moment(i, "lesser", mf) for i in range(2*
n_initial+2)]
2 moments_great = [form_moment(i, "greater", mf) for i in range(2*
n_initial+2)]
3 L_less = np.linalg.cholesky(moments_less[0], upper=False)
4 L_great = np.linalg.cholesky(moments_great[0], upper=False)
5 L = (L_less, L_great)
```

Then, we can construct the spectral function via

$$A(\omega) = \sum_k \|\boldsymbol{\psi}_k\|^2 \underbrace{\frac{1}{\pi} \frac{\eta}{(\omega - E_k)^2 + \eta^2}}_{\text{Lorentzian}} \quad (2.89)$$

where η is a broadening parameter. In general, the spectral function is known to have the form

$$A(\omega) = -\frac{1}{\pi} \text{Im} G(\omega) \quad (2.90)$$

and the Dyson equation is

$$G(\omega) = G_0(\omega) + G_0(\omega) \Sigma(\omega) G(\omega) = \frac{1}{\underbrace{\omega - \epsilon_0}_{G_0(\omega)^{-1}} - \Sigma(\omega)} \quad (2.91)$$

but then we know that $\Sigma(\omega) = \Sigma_R(\omega) + i\Sigma_I(\omega)$, so we can write

$$G(\omega) = \frac{1}{\omega - \epsilon_0 - \Sigma_R(\omega) - i\Sigma_I(\omega)} \quad (2.92)$$

Defining $x(\omega) = \omega - \epsilon_0 - \Sigma_R(\omega)$ and $y(\omega) = \Sigma_I(\omega)$, we can rewrite the Dyson equation as

$$G(\omega) = \frac{1}{x(\omega) - iy(\omega)} \times \frac{x(\omega) + iy(\omega)}{x(\omega) + iy(\omega)} = \frac{x(\omega) + iy(\omega)}{(x(\omega))^2 + (y(\omega))^2} \implies \text{Im} G(\omega) = \frac{y(\omega)}{(x(\omega))^2 + (y(\omega))^2} \quad (2.93)$$

We have the following fully analytic expression for the self-energy

$$\Sigma_{pp}^{\text{corr}}(\omega) = \sum_{\mu}^{\text{RPA}} \left(\sum_i^{\text{occupied}} \frac{w_{pi}^{\mu} w_{ip}^{\mu}}{\omega - (\epsilon_i - \Omega_{\mu}) + i\eta} + \sum_a^{\text{virtual}} \frac{w_{pa}^{\mu} w_{ap}^{\mu}}{\omega - (\epsilon_a + \Omega_{\mu}) - i\eta} \right) \quad (2.94)$$

with

$$w_{pq}^\mu = \sum_{jb} (pq|jb) (X_{jb}^\mu + Y_{jb}^\mu) \quad (2.95)$$

So

$$\Sigma_{pp}^R(\omega) = \sum_{\mu}^{\text{RPA}} \left(\sum_i^{\text{occupied}} \frac{w_{pi}^\mu w_{ip}^\mu}{\omega - (\epsilon_i - \Omega_\mu)} + \sum_a^{\text{virtual}} \frac{w_{pa}^\mu w_{ap}^\mu}{\omega - (\epsilon_a + \Omega_\mu)} \right) \quad (2.96)$$

and because $\frac{1}{\omega \pm i\eta} = \mathcal{P} \frac{1}{\omega} \mp i\pi\delta(\omega)$, we can write

$$\Sigma_{pp}^I(\omega) = \pi \sum_{\mu}^{\text{RPA}} \left(\sum_a^{\text{virtual}} w_{pa}^\mu w_{ap}^\mu \delta(\omega - (\epsilon_a + \Omega_\mu)) - \sum_i^{\text{occupied}} w_{pi}^\mu w_{ip}^\mu \delta(\omega - (\epsilon_i - \Omega_\mu)) \right) \quad (2.97)$$

This brings us back to a Lorentzian

$$A(\omega) = -\frac{1}{\pi} \sum_p \frac{\eta(\omega)}{(\omega - \epsilon_0 - \Sigma_{pp}^R(\omega))^2 + \eta(\omega)^2} \quad (2.98)$$

with $\eta(\omega) \equiv \Sigma_{pp}^I(\omega)$. We need to compute

$$\eta(\omega) = \left(\sum_{\mu}^{\text{RPA}} \left(\sum_a^{\text{virtual}} w_{pa}^\mu w_{ap}^\mu \left(\frac{\gamma}{(\omega - (\epsilon_a + \Omega_\mu))^2 + \gamma^2} \right) - \sum_i^{\text{occupied}} w_{pi}^\mu w_{ip}^\mu \left(\frac{\gamma}{(\omega - (\epsilon_i - \Omega_\mu))^2 + \gamma^2} \right) \right) \right)_p \quad (2.99)$$

at each $\omega = E_{QP}$ that we found in the QP equation. Meanwhile, we know that the QP renormalization factor is given by

$$Z_p = \left(1 - \frac{\partial \Sigma_{pp}^R(\omega)}{\partial \omega} \Big|_{\omega=E_{QP}} \right)^{-1} \quad (2.100)$$

So I need to prove the equivalence between this form and the one I have above using $\eta(\omega)$.

2.7 6/2 Conclusions

2.7.1 Hypothesis

If one maintains orthogonality in the Krylov subspace, the Ritz eigenpairs will converge to exact diagonalization within numerical precision. However, it is a fact that if the residual of the recurrence relation 2.113 loses full rank, the off-diagonal elements get a high condition number and are no longer invertible. So we have seen that MC-GW can replicate the block Lanczos up until this condition is met, but no longer afterwards. So even though MC-GW enforces orthogonality of the Krylov subspace even after the residual does lose its full rank, the off-diagonal elements are then no longer invertible, which explains the numerical issues that I observe after this point.

2.7.2 Systems of Study

Given my physical dimension n_{occ} , the auxiliary dimension is of size $n_{\text{channel}} \times n_{\text{virt}} \times n_{\text{occ}}$, where n_{channel} is either n_{occ} or n_{virt} , depending on whether we are dealing with the lesser or greater channel; it becomes clear that the block size, which is determined by the physical dimension, will be $O(n_{\text{occ}})$, whereas the size of the auxiliary dimension will be $O(n_{\text{channel}} \times n_{\text{virt}} \times n_{\text{occ}})$. I have been doing my tests up until now with a minimal basis, where at least one of these n s is small, so I wonder if when I move to a larger basis there will be a noticeable difference with the large discrepancy between n and n^3 . Perhaps we will be able to exactly converge the low-lying orbital MO QPEs, but not the higher ones, but this is typically all that is desired of the method.

2.8 6/10 plots

As you probably have seen, in the theory of MC-GW, the equations come in two forms; the first gives the explicit definition of the quantity in terms of a projection on the Krylov subspace and the second gives the recurrence relation that is used in MC-GW.

$$\mathbf{S}_{i+1,i}^n \equiv \mathbf{q}_{i+1}^\dagger \mathbf{d}^n \mathbf{q}_i = \mathbf{C}_i^{-1} \left[\mathbf{S}_{i,i}^{n+1} - \mathbf{M}_i \mathbf{S}_{i,i}^n - \mathbf{C}_{i-1}^\dagger \mathbf{S}_{i-1,i}^n \right] \quad (2.101)$$

or

$$\begin{aligned} \mathbf{S}_{i+1,i+1}^n \equiv \mathbf{q}_{i+1}^\dagger \mathbf{d}^n \mathbf{q}_{i+1} = \mathbf{C}_i^{-1} \left[\mathbf{S}_{i,i}^{n+2} + \mathbf{M}_i \mathbf{S}_{i,i}^n \mathbf{M}_i + \mathbf{C}_{i-1}^\dagger \mathbf{S}_{i-1,i-1}^n \mathbf{C}_{i-1} \right. \\ \left. - P(\mathbf{S}_{i,i}^{n+1} \mathbf{M}_i) - P(\mathbf{S}_{i,i-1}^{n+1} \mathbf{C}_{i-1}) + P(\mathbf{M}_i \mathbf{S}_{i,i-1}^n \mathbf{C}_{i-1}) \right] \mathbf{C}_i^{\dagger,-1} \end{aligned} \quad (2.102)$$

or

$$\mathbf{C}_i^2 = \mathbf{C}_i \mathbf{C}_i^\dagger = \mathbf{S}_{i,i}^2 + \mathbf{M}_i^2 + \mathbf{C}_{i-1}^\dagger \mathbf{C}_{i-1} - P(\mathbf{S}_{i,i}^1 \mathbf{M}_i) - P(\mathbf{S}_{i,i-1}^1 \mathbf{C}_{i-1}) \quad (2.103)$$

$$(2.104)$$

with

$$\mathbf{C}_i = \mathbf{q}_i^\dagger \mathbf{d} \mathbf{q}_{i+1} \quad (2.105)$$

The curve that I label as MCGW dense corresponds to the middle equality, MCGW sparse corresponds to the right equality, and the black curve is the standard block Lanczos with matrix vector products. Then, I also display the solution that Booth code gives. There is a reason why I am not able to get the MCGW sparse curve to match the dense curve. Recall that to solve 2.107, we want to perform a Cholesky decomposition of the matrix \mathbf{C}_i^2 to get \mathbf{C}_i . So the matrix should be symmetric and also positive semidefinite. I always begin by trying to use the modified Cholesky algorithm to perform this matrix square root. However, even in the exact dense theory, the matrix \mathbf{C}_i^2 is not always even positive semidefinite (it has negative eigenvalues), so I cannot use the modified Cholesky algorithm to solve in that case. In addition, due to the rise in numerical imprecision, the matrix also becomes non-symmetric, so in these cases I just symmetrize it, get the eigendecomposition, and do the matrix square root that way. But in exact arithmetic, this is a Hermitian theory, so I shouldn't have to symmetrize like this and in doing so I introduce some error. As can be seen, this gives a fairly good match with what Booth codes predict; we are probably doing similar things.

2.9 Canonical orthogonalization

The numerical issue with the theory of MCGW seems to lie with then obtaining the appropriate off-diagonals from

$$C_i^2 = C_i C_i^\dagger = S_{i,i}^2 + M_i^2 + C_{i-1}^\dagger C_{i-1} - P(S_{i,i}^1 M_i) - P(S_{i,i-1}^1 C_{i-1}) \quad (2.106)$$

$$(2.107)$$

Let us now try to achieve the same result using canonical orthogonalization. Once we build C_i^2 we can take the eigendecomposition of the matrix to get

$$C_i^2 = U_i \Lambda_i U_i^\dagger \quad (2.108)$$

2.10 Krylov subspace orthogonality contradiction

2.10.1 Theoretical background

There seems to be a contradiction regarding the orthogonality of the Krylov vectors in MCGW. We know that I am able to see convergence to ED to within machine precision when I explicitly build up a Krylov subspace, taking care to ensure orthogonality between Krylov vectors, by both doing Gram-Schmidt on each new vector with all previous ones and then throwing away the small singular values if there is a lack of new directions. This is the exact block Lanczos with matrix vector products curve that I sent Tuesday. Now, MCGW claims to enforce orthogonality in the Krylov subspace by doing $S_{i,j}^{(0)} = \delta_{ij} \mathbf{I}$ with

$$S_{i,j}^{(n)} = \mathbf{q}_i^\dagger \mathbf{d}^n \mathbf{q}_j \quad (2.109)$$

This is what rationalizes the simplification in the rewriting of the coupling block \mathbf{W} as \mathbf{R} padded with 0s. For a brief refresher, see the flow in the equations below in the example of a Krylov subspace which is containing only two block vectors.

$$\tilde{H}_{\text{unfolded}}^{\text{Lanczos Iter 2}} = \tilde{Q}^{(2,\dagger)} H_{\text{Upfolded}}^{G_0 W_0} \tilde{Q}^{(2)} \quad (2.110)$$

$$= \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & [\mathbf{q}_1^\dagger & \mathbf{q}_2^\dagger] \end{pmatrix} \begin{pmatrix} \mathbf{F} + \Sigma(\infty) & \mathbf{W} \\ \mathbf{W}^\dagger & \mathbf{d} \end{pmatrix} \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & [\mathbf{q}_1 & \mathbf{q}_2] \end{pmatrix} \quad (2.111)$$

$$= \begin{pmatrix} \mathbf{F} + \Sigma(\infty) & \begin{bmatrix} \underbrace{\mathbf{W} \mathbf{q}_1}_{\mathcal{R} \mathcal{Q}^\dagger \mathcal{Q} = \mathcal{R}} & \underbrace{\mathbf{W} \mathbf{q}_2}_{\mathbf{0}} \end{bmatrix} \\ \begin{bmatrix} \underbrace{\mathbf{q}_1^\dagger \mathbf{W}^\dagger}_{\mathcal{Q}^\dagger \mathcal{Q} \mathcal{R}^\dagger = \mathcal{R}^\dagger} & \underbrace{\mathbf{q}_2^\dagger \mathbf{W}^\dagger}_{\mathbf{0}} \end{bmatrix} & \begin{pmatrix} \underbrace{\mathbf{q}_1^\dagger \mathbf{d} \mathbf{q}_1}_{M_1} & \underbrace{\mathbf{q}_1^\dagger \mathbf{d} \mathbf{q}_2}_{C_1} \\ \underbrace{\mathbf{q}_2^\dagger \mathbf{d} \mathbf{q}_1}_{C_1^\dagger} & \underbrace{\mathbf{q}_2^\dagger \mathbf{d} \mathbf{q}_2}_{M_2} \end{pmatrix} \end{pmatrix} \quad (2.112)$$

But now recall that MCGW relies on the three-term Lanczos recurrence of

$$\mathbf{q}_{i+1} \mathbf{C}_i^\dagger = [\mathbf{d} \mathbf{q}_i - \mathbf{q}_i \mathbf{M}_i - \mathbf{q}_{i-1} \mathbf{C}_{i-1}] \implies \mathbf{q}_{i+1} = [\mathbf{d} \mathbf{q}_i - \mathbf{q}_i \mathbf{M}_i - \mathbf{q}_{i-1} \mathbf{C}_{i-1}] \mathbf{C}_i^{\dagger,-1} \quad (2.113)$$

which is used in the definition of the \mathbf{S} es. Crucially, orthogonality is never enforced in these relations, so after sufficient iterations we get $\mathbf{q}_i^\dagger \mathbf{q}_j \neq 0$ for $i \neq j$. This is in contradiction with our initial assumption that the coupling block \mathbf{W} can be written as \mathbf{R} padded with zeros. So it is perfectly natural to not see MCGW converge to ED to within machine precision as is seen in the MCGW sparse curve of my plots. Recall that the MCGW dense curve was obtained by explicitly plugging in the Krylov vector from the exact block Lanczos with matrix vector products into 2.109; this was done with genuinely orthogonalized Krylov vectors and hence we saw an exact convergence to ED similar to that of the matrix vector product implementation.

2.10.2 Comment about the effect of minimal basis

It is true that the fact that I was experiencing a lack of new directions was an artifact of me using a minimal basis in my calculations. This put the size of the physical space, which scales as $O(O + V)$, on par with the auxiliary space, which scales as $O(O^2V)$ or $O(V^2O)$, depending on whether we are dealing with the lesser or greater channel, respectively. The dimension of the auxiliary space will grow faster than that of the physical space as we move to larger system sizes, so it is expected that this effect would be negligible by using a larger basis in my calculation. However, this does not solve the issue of not being able to maintain orthogonality by doing Gram-Schmidt of a new vector on all previous vectors. But, I did a numerical tests of the effect of a lack of reorthogonalization on the Ritz values a few months ago, and the effect was negligible.

2.10.3 Next steps

Should I run this with double zeta basis in C++? At the end of the day, I have just speculated, and I haven't proven anything, so it would be nice to see if what I hypothesis plays out in practice.

2.11 A hierarchy of approximations to block Lanczos with reorthogonalization

To simplify the discussion, I will just consider a single channel here.

2.11.1 Exact solution

The QP energies are given by diagonalizing the upfolded Hamiltonian

$$\mathbf{H}_{\text{upfolded}} = \begin{pmatrix} \mathbf{F} & \mathbf{W} \\ \mathbf{W}^\dagger & \mathbf{d} \end{pmatrix} \quad (2.114)$$

We can accomplish the same thing by considering the Ritz values as obtained by projecting the unfolded Hamiltonian, which is called exact \mathbf{d} , onto an orthonormal Krylov subspace as

$$\tilde{\mathbf{H}}_{\text{unfolded}}^{\text{Lanczos Iter 3}} = \tilde{\mathbf{Q}}^{(3,\dagger)} \mathbf{H}_{\text{unfolded}} \tilde{\mathbf{Q}}^{(3)} \quad (2.115)$$

$$= \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & [\mathbf{q}_1^\dagger & \mathbf{q}_2^\dagger & \mathbf{q}_3^\dagger] \end{pmatrix} \begin{pmatrix} \mathbf{F} & \mathbf{W} \\ \mathbf{W}^\dagger & \mathbf{d} \end{pmatrix} \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & [\mathbf{q}_1 & \mathbf{q}_2 & \mathbf{q}_3] \end{pmatrix} \quad (2.116)$$

$$= \begin{pmatrix} \mathbf{F} & \begin{bmatrix} \underbrace{\mathbf{W}\mathbf{q}_1}_{\mathcal{R}\mathbf{q}_1^\dagger\mathbf{q}_1=\mathcal{R}} & \underbrace{\mathbf{W}\mathbf{q}_2}_{\mathcal{R}\mathbf{q}_1^\dagger\mathbf{q}_2=0} & \underbrace{\mathbf{W}\mathbf{q}_3}_{\mathcal{R}\mathbf{q}_1^\dagger\mathbf{q}_3=0} \end{bmatrix} \\ \begin{bmatrix} \underbrace{\mathbf{q}_1^\dagger\mathbf{W}^\dagger}_{\mathbf{q}_1^\dagger\mathbf{q}_1\mathcal{R}^\dagger=\mathcal{R}^\dagger} & \underbrace{\mathbf{q}_2^\dagger\mathbf{W}^\dagger}_{\mathbf{q}_1^\dagger\mathbf{q}_2\mathcal{R}^\dagger=0^\dagger} & \underbrace{\mathbf{q}_3^\dagger\mathbf{W}^\dagger}_{\mathbf{q}_1^\dagger\mathbf{q}_3\mathcal{R}^\dagger=0^\dagger} \end{bmatrix} & \begin{pmatrix} \underbrace{\mathbf{q}_1^\dagger\mathbf{d}\mathbf{q}_1}_{M_1} & \underbrace{\mathbf{q}_1^\dagger\mathbf{d}\mathbf{q}_2}_{C_1} & \underbrace{\mathbf{q}_1^\dagger\mathbf{d}\mathbf{q}_3}_0 \\ \underbrace{\mathbf{q}_2^\dagger\mathbf{d}\mathbf{q}_1}_{C_1^\dagger} & \underbrace{\mathbf{q}_2^\dagger\mathbf{d}\mathbf{q}_2}_{M_2} & \underbrace{\mathbf{q}_2^\dagger\mathbf{d}\mathbf{q}_3}_{C_2} \\ \underbrace{\mathbf{q}_3^\dagger\mathbf{d}\mathbf{q}_1}_0 & \underbrace{\mathbf{q}_3^\dagger\mathbf{d}\mathbf{q}_2}_{C_2^\dagger} & \underbrace{\mathbf{q}_3^\dagger\mathbf{d}\mathbf{q}_3}_{M_3} \end{pmatrix} \end{pmatrix} \quad (2.117)$$

This is what the matrix-vector product and exact \mathbf{d} both do when we apply reorthogonalization.

2.11.2 Matrix-vector product without reorthogonalization

This is one step down from the exact answer. The only reason that we are able to set $\mathbf{q}_i\mathbf{d}\mathbf{q}_j = \mathbf{0}$ for $i > j + 1$ in 2.117 is because we are assuming an orthogonal basis where

$$\mathbf{d}\mathbf{q}_j = \mathbf{C}_{j-1}\mathbf{q}_{j-1} + \mathbf{M}_j\mathbf{q}_j + \mathbf{C}_{j+1}\mathbf{q}_{j+1} \implies \mathbf{q}_{j+2}^\dagger\mathbf{d}\mathbf{q}_j = \mathbf{q}_{j+2}^\dagger \left(\mathbf{C}_{j-1}^\dagger\mathbf{q}_{j-1} + \mathbf{M}_j^\dagger\mathbf{q}_j + \mathbf{C}_{j+1}^\dagger\mathbf{q}_{j+1} \right) = \mathbf{0} \quad (2.118)$$

We will call this assumption 1. But in general, with a non-orthogonal basis, we have

$$\mathbf{d}\mathbf{q}_j = \sum_{\ell=1}^{j+1} \mathbf{H}_{j,\ell} \mathbf{q}_\ell. \quad (2.119)$$

This becomes the case after a few Lanczos iterations, which I have shown before. However, the fact that we have written the coupling block as \mathbf{R} padded with zeros (I will refer to this as assumption 2) is consistent with the way that we have constructed the auxiliary block, so even though we have violated assumption 1, assumption 2 still holds, and we get results one level down from the exact solution.

2.11.3 Exact \mathbf{d} without reorthogonalization

Because this is just projecting \mathbf{d} onto an increasingly non-orthogonal Krylov subspace, we are no longer making assumption 1. To make it more clear what I mean here, consider that we are no longer assuming a tridiagonal form for the auxiliary block in 2.117, as we are allowing for nonzero $\mathbf{q}_i\mathbf{d}\mathbf{q}_j$ with $i > j + 1$. But now we are violating assumption 2, which

is why this gives different results than 2.11.2. **Do we want to understand under what conditions approximation 1 seems to do better than 2, and if so, then how? It doesn't seem to matter in the context of MC-GW, but maybe you have a broader vision.**

2.11.4 MCGW with recurrence relation

In our derivation of the extended recurrence relation, there were 3 instances where we assumed that we could substitute in our expression for \mathbf{q}_{j+1} from 2.118 as

$$\mathbf{q}_{i+1} = [\mathbf{d}\mathbf{q}_i - \mathbf{q}_i\mathbf{M}_i - \mathbf{q}_{i-1}\mathbf{C}_{i-1}] \mathbf{C}_i^{\dagger,-1} \quad (2.120)$$

2 were when defined a $\mathbf{S}_{i+1,i+1}^n$ and 1 was when we defined $\mathbf{S}_{i+1,i}^n$. This uses more approximations than 2.11.3, so it makes sense that we get worse results.

2.12 Next steps

I have a C++ code that I can run now for the dzvp basis, but it is still too slow, which was why I was only able to show you a limited amount of results last time. I will talk to people in the group about how to make it faster. I guess you want me to generate plots like this one for the larger system sizes.

Chapter 3

Berkelbach's GW

3.1 Formulation for the TDA

3.1.1 Definitions

For simplicity, we will just work with a single channel, the lesser one. In the dTDA case, Booth's formulation for the upfolded Hamiltonian is

$$\mathbf{H} = \begin{pmatrix} \mathbf{F} & \mathbf{W} \\ \mathbf{W}^\dagger & \mathbf{d} \end{pmatrix} \quad (3.1)$$

where we have the definitions

$$W_{pkv} = \sum_{ia} (pk|ia) X_{ia}^v \quad \text{and} \quad d_{kv,lv'} = (\epsilon_k - \Omega_v) \delta_{k,l} \delta_{v,v'} \quad (3.2)$$

Now, Tim's version of the Hamiltonian is given by

$$\mathbf{H} = \begin{pmatrix} \mathbf{F} & \mathbf{V}^{2\text{h1p}} \\ (\mathbf{V}^{2\text{h1p}})^\dagger & \mathbf{C}^{2\text{h1p}} \end{pmatrix} \quad (3.3)$$

where the definitions of the matrix elements are

$$V_{p,k[lc]}^{2\text{h1p}} = \langle pc|kl \rangle \equiv (pk|lc) \quad (3.4)$$

$$C_{i[ja],k[lc]}^{2\text{h1p}} = [(\epsilon_i + \epsilon_j - \epsilon_a) \delta_{jl} \delta_{ac} - \langle jc|al \rangle] \delta_{ik} \quad (3.5)$$

and in particular, we have a definition

$$\mathbf{C}^{2\text{h1p}} = \epsilon^{1\text{h}} \oplus (-\mathbf{A}) = \epsilon^{1\text{h}} \otimes \mathbf{1} + \mathbf{1} \otimes (-\mathbf{A}) \quad (3.6)$$

Let us show how 3.5 comes from 3.6. If $A_{[ja],[lc]} = (\epsilon_j - \epsilon_a) \delta_{jl} \delta_{ac} + \langle jc|al \rangle$, then we can write

$$C_{i[ja],k[lc]}^{2\text{h1p}} = [\epsilon_i \delta_{ik} \delta_{jl} \delta_{ac} + (-A)_{[ja],[lc]}] \quad (3.7)$$

$$= \delta_{ik} [\epsilon_i \delta_{jl} \delta_{ac} + (-A)_{[ja],[lc]}] \quad (3.8)$$

$$= \delta_{ik} [(\epsilon_i + \epsilon_j - \epsilon_a) \delta_{jl} \delta_{ac} - \langle jc|al \rangle] \quad (3.9)$$

3.1.2 Similarity transformation

Let us define a unitary rotation $U = \mathbf{1}_P \oplus_{\text{diag}} (\mathbf{1}_O \otimes \mathbf{X}_{OV})$. Application of this unitary to the Hamiltonian will not change the spectrum and actually transforms the problem into

$$\mathbf{H}' = U^\dagger \mathbf{H} U = \begin{pmatrix} \mathbf{1}_P & \mathbf{0} \\ \mathbf{0} & (\mathbf{1}_O \otimes \mathbf{X}_{OV}) \end{pmatrix}^\dagger \begin{pmatrix} \mathbf{F}_P & \mathbf{V}_{P,O^2V}^{2\text{h1p}} \\ (\mathbf{V}^{2\text{h1p}})_{O^2V,P}^\dagger & \mathbf{C}_{O^2V,O^2V}^{2\text{hlp}} \end{pmatrix} \begin{pmatrix} \mathbf{1}_P & \mathbf{0} \\ \mathbf{0} & (\mathbf{1}_O \otimes \mathbf{X}_{OV}) \end{pmatrix} \quad (3.10)$$

$$= \begin{pmatrix} \mathbf{F}_P & \mathbf{V}_{P,O^2V}^{2\text{h1p}} (\mathbf{1} \otimes \mathbf{X})_{O^2V,O^2V} \\ \left(\mathbf{V}_{P,O^2V}^{2\text{h1p}} (\mathbf{1} \otimes \mathbf{X})_{O^2V,O^2V} \right)^\dagger & \left((\mathbf{1} \otimes \mathbf{X})_{O^2V,O^2V} \right)^\dagger \mathbf{C}_{O^2V,O^2V}^{2\text{hlp}} (\mathbf{1} \otimes \mathbf{X})_{O^2V,O^2V} \end{pmatrix}. \quad (3.11)$$

Now let us evaluate $(\mathbf{1} \otimes \mathbf{X})^\dagger \mathbf{C}^{2\text{hlp}} (\mathbf{1} \otimes \mathbf{X})$ in the TDA case. We have

$$(\mathbf{1} \otimes \mathbf{X})^\dagger \mathbf{C}^{2\text{hlp}} (\mathbf{1} \otimes \mathbf{X}) = (\mathbf{1} \otimes \mathbf{X})^\dagger [\epsilon^{1\text{ h}} \otimes \mathbf{1} + \mathbf{1} \otimes (-\mathbf{A})] (\mathbf{1} \otimes \mathbf{X}) \quad (3.12)$$

$$= (\mathbf{1} \otimes \mathbf{X}^\dagger) [\epsilon^{1\text{ h}} \otimes \mathbf{1}] (\mathbf{1} \otimes \mathbf{X}) + (\mathbf{1} \otimes \mathbf{X}^\dagger) [\mathbf{1} \otimes (-\mathbf{A})] (\mathbf{1} \otimes \mathbf{X}) \quad (3.13)$$

$$= \mathbf{1} \epsilon^{1\text{ h}} \mathbf{1} \otimes \mathbf{X}^\dagger \mathbf{1} \mathbf{X} + \mathbf{1} \mathbf{1} \mathbf{1} \otimes (-\mathbf{X}^\dagger \mathbf{A} \mathbf{X}) \quad (3.14)$$

$$= \epsilon^{1\text{ h}} \otimes \mathbf{1} + \mathbf{1} \otimes (-\mathbf{X}^\dagger \mathbf{A} \mathbf{X}) \quad (3.15)$$

$$= \epsilon^{1\text{ h}} \otimes \mathbf{1} + \mathbf{1} \otimes (-\Omega) \quad (3.16)$$

$$= \epsilon^{1\text{ h}} \oplus (-\Omega) \quad (3.17)$$

where we have used the fact that $\mathbf{X}^\dagger \mathbf{X} = \mathbf{1}$, since \mathbf{X} is unitary. Similarly, we can evaluate the other term

$$\mathbf{V}_{P,O^2V}^{2\text{h1p}} (\mathbf{1} \otimes \mathbf{X})_{O^2V,O^2V} = \sum_{k'lc} (pk|lc) X_{lc}^v \delta_{kk'} \quad (3.18)$$

$$= \sum_{lc} (pk|lc) X_{lc}^v \equiv \mathbf{W}^< \quad (3.19)$$

$$(3.20)$$

So because Booth's and Tim's forms for TDA are related by a similarity transformation, we know that they have the same spectrum.

3.1.3 Deriving the matrix vector products

Now, we can define a vector $\mathbf{R} = (r_i, r_a, r_{i[jb]}, r_{[jb]a})$. Application of the Hamiltonian to this vector gives us the matrix-vector product $\mathbf{H}\mathbf{R} = \boldsymbol{\sigma}$, where $\boldsymbol{\sigma} = (\sigma_i, \sigma_a, \sigma_{i[jb]}, \sigma_{[jb]a})$. Consider

$$\mathbf{H}\mathbf{R} = \begin{pmatrix} \mathbf{F} & \mathbf{V}^{2\text{h1p}} & \mathbf{V}^{2\text{p1 h}} \\ (\mathbf{V}^{2\text{h1p}})^\dagger & \mathbf{C}^{2\text{hlp}} & \mathbf{0} \\ (\mathbf{V}^{2\text{plh}})^\dagger & \mathbf{0} & \mathbf{C}^{2\text{plh}} \end{pmatrix} \begin{pmatrix} r_i \\ r_a \\ r_{i[jb]} \\ r_{[jb]a} \end{pmatrix} = \begin{pmatrix} \sigma_i \\ \sigma_a \\ \sigma_{i[jb]} \\ \sigma_{[jb]a} \end{pmatrix} \quad (3.21)$$

$$(3.22)$$

Let us enumerate now what we actually will get:

$$\sigma_i = \sum_j f_{ij} r_j + \sum_b f_{ib} r_b + \sum_{klc} \langle i c | k l \rangle r_{k[lc]} + \sum_{kcd} \langle i k | d c \rangle r_{[kc]d}, \quad (3.23)$$

$$\sigma_a = \sum_j f_{aj} r_j + \sum_b f_{ab} r_b + \sum_{klc} \langle a c | k l \rangle r_{k[lc]} + \sum_{kcd} \langle a k | d c \rangle r_{[kc]d}, \quad (3.24)$$

$$\sigma_{i[ja]} = \sum_k \langle k a | i j \rangle r_k + \sum_b \langle b a | i j \rangle r_b + (\epsilon_i + \epsilon_j - \epsilon_a) r_{i[ja]} - \sum_{lc} \langle j c | a l \rangle r_{i[lc]} \quad (3.25)$$

$$\sigma_{[ia]b} = \sum_j \langle j i | b a \rangle r_j + \sum_c \langle c i | b a \rangle r_c + (\epsilon_a + \epsilon_b - \epsilon_i) r_{[ia]b} + \sum_{kc} \langle a k | i c \rangle r_{[kc]b}. \quad (3.26)$$

3.2 Formulation for the dRPA

Exact form

The exact form is

$$\mathbf{H}_{\text{Upfolded}}^{G_0 W_0} = \begin{pmatrix} \mathbf{F} & \mathbf{W}^< & \mathbf{W}^> \\ \mathbf{W}^{<,\dagger} & \mathbf{d}^< & 0 \\ \mathbf{W}^{>,\dagger} & 0 & \mathbf{d}^> \end{pmatrix} \quad (3.27)$$

where \mathbf{F} is the HF Fock matrix

$$\mathbf{W}_{pk\nu}^< = \sum_{ia} (pk|ia) (X_{ia}^\nu + Y_{ia}^\nu) \quad \text{and} \quad \mathbf{W}_{pc\nu}^> = \sum_{ia} (pc|ia) (X_{ia}^\nu + Y_{ia}^\nu) \quad (3.28)$$

and

$$\mathbf{d}_{k\nu,l\nu'}^< = (\epsilon_k - \Omega_\nu) \delta_{k,l} \delta_{\nu,\nu'} \quad \text{and} \quad \mathbf{d}_{c\nu,d\nu'}^> = (\epsilon_c + \Omega_\nu) \delta_{c,d} \delta_{\nu,\nu'}. \quad (3.29)$$

Downfolding exercise

Let us confirm that this downfolds to the correct result. First, we can define a excitation vector \mathbf{R} as

$$\mathbf{R} = \begin{pmatrix} \mathbf{R}^{1h+1p} \\ \mathbf{R}^{2h1p} \\ \mathbf{R}^{2p1h} \end{pmatrix} \quad (3.30)$$

and we can write

$$\begin{pmatrix} \mathbf{F} & \mathbf{W}^< & \mathbf{W}^> \\ \mathbf{W}^{<,\dagger} & \mathbf{d}^< & 0 \\ \mathbf{W}^{>,\dagger} & 0 & \mathbf{d}^> \end{pmatrix} \begin{pmatrix} \mathbf{R}^{1h+1p} \\ \mathbf{R}^{2h1p} \\ \mathbf{R}^{2p1h} \end{pmatrix} = E \begin{pmatrix} \mathbf{R}^{1h+1p} \\ \mathbf{R}^{2h1p} \\ \mathbf{R}^{2p1h} \end{pmatrix} \quad (3.31)$$

$$\begin{pmatrix} \mathbf{F}\mathbf{R}^{1h+1p} + \mathbf{W}^< \mathbf{R}^{2h1p} + \mathbf{W}^> \mathbf{R}^{2p1h} \\ \mathbf{W}^{<,\dagger} \mathbf{R}^{1h+1p} + \mathbf{d}^< \mathbf{R}^{2h1p} \\ \mathbf{W}^{>,\dagger} \mathbf{R}^{1h+1p} + \mathbf{d}^> \mathbf{R}^{2p1h} \end{pmatrix} = E \begin{pmatrix} \mathbf{R}^{1h+1p} \\ \mathbf{R}^{2h1p} \\ \mathbf{R}^{2p1h} \end{pmatrix} \quad (3.32)$$

This implies three coupled equations

$$\mathbf{F}\mathbf{R}^{1h+1p} + \mathbf{W}^< \mathbf{R}^{2h1p} + \mathbf{W}^> \mathbf{R}^{2p1h} = E\mathbf{R}^{1h+1p} \quad (3.33)$$

$$\mathbf{W}^{<,\dagger} \mathbf{R}^{1h+1p} + \mathbf{d}^< \mathbf{R}^{2h1p} = E\mathbf{R}^{2h1p} \quad (3.34)$$

$$\mathbf{W}^{>,\dagger} \mathbf{R}^{1h+1p} + \mathbf{d}^> \mathbf{R}^{2p1h} = E\mathbf{R}^{2p1h} \quad (3.35)$$

Solving the latter two equations gives

$$\mathbf{R}^{2h1p} = (E\mathbf{1} - \mathbf{d}^<)^{-1} \mathbf{W}^{<,\dagger} \mathbf{R}^{1h+1p} \quad (3.36)$$

$$\mathbf{R}^{2p1h} = (E\mathbf{1} - \mathbf{d}^>)^{-1} \mathbf{W}^{>,\dagger} \mathbf{R}^{1h+1p} \quad (3.37)$$

Substituting these into the first equation gives us

$$\mathbf{F}\mathbf{R}^{1h+1p} + \mathbf{W}^< (E\mathbf{1} - \mathbf{d}^<)^{-1} \mathbf{W}^{<,\dagger} \mathbf{R}^{1h+1p} + \mathbf{W}^> (E\mathbf{1} - \mathbf{d}^>)^{-1} \mathbf{W}^{>,\dagger} \mathbf{R}^{1h+1p} = E\mathbf{R}^{1h+1p} \quad (3.38)$$

from which we can get the eigenvalue equation

$$\left(\mathbf{F} + \mathbf{W}^< (E\mathbf{1} - \mathbf{d}^<)^{-1} \mathbf{W}^{<,\dagger} + \mathbf{W}^> (E\mathbf{1} - \mathbf{d}^>)^{-1} \mathbf{W}^{>,\dagger} \right) \mathbf{R}^{1h+1p} = E\mathbf{R}^{1h+1p} \quad (3.39)$$

so we can identify that the correlation self energy in this approach is

$$\Sigma_c = \mathbf{W}^< (\omega\mathbf{1} - \mathbf{d}^<)^{-1} \mathbf{W}^{<,\dagger} + \mathbf{W}^> (\omega\mathbf{1} - \mathbf{d}^>)^{-1} \mathbf{W}^{>,\dagger} \quad (3.40)$$

which is the same as the known frequency dependent form for the real part of the correlation self energy:

$$\Sigma_{pq}^{\text{corr}}(\omega) = \sum_{\mu}^{\text{RPA}} \left(\sum_i^{\text{occupied}} \frac{w_{pi}^{\mu} w_{iq}^{\mu}}{\omega - (\epsilon_i - \Omega_{\mu})} + \sum_a^{\text{virtual}} \frac{w_{pa}^{\mu} w_{aq}^{\mu}}{\omega - (\epsilon_a + \Omega_{\mu})} \right) \quad (3.41)$$

with $w_{pq}^{\mu} = \sum_{ia} (pq|ia) (X_{ia}^{\mu} + Y_{ai}^{\mu})$.

Showing equivalence between excitation energies of \mathbf{M} and \mathbf{M} tilde

So we start with this generalized eigenvalue equation

$$\mathbf{M}\mathbf{Z} = \mathbf{N}\mathbf{Z} \begin{pmatrix} \Omega_+ & 0 \\ 0 & -\Omega_+ \end{pmatrix}$$

where

$$\mathbf{M} = \begin{pmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{B} & \mathbf{A} \end{pmatrix} \quad \mathbf{N} = \begin{pmatrix} \mathbf{1} & \mathbf{0} \\ \mathbf{0} & -\mathbf{1} \end{pmatrix} \quad \mathbf{Z} = \begin{pmatrix} \mathbf{X} & \mathbf{Y} \\ \mathbf{Y} & \mathbf{X} \end{pmatrix}$$

and Ω_+ is a diagonal matrix of positive excitation energies. Left multiplying both sides by \mathbf{N} and right multiplying by \mathbf{Z}^{-1} gives us

$$\mathbf{N}\mathbf{M} \underbrace{\mathbf{Z}\mathbf{Z}^{-1}}_{\mathbf{1}} = \underbrace{\mathbf{N}\mathbf{N}}_{\mathbf{1}} \mathbf{Z} \begin{pmatrix} \Omega_+ & 0 \\ 0 & -\Omega_+ \end{pmatrix} \mathbf{Z}^{-1} \implies -\mathbf{N}\mathbf{M} = -\mathbf{Z} \begin{pmatrix} \Omega_+ & 0 \\ 0 & -\Omega_+ \end{pmatrix} \mathbf{Z}^{-1} \quad (3.42)$$

Now we can use the fact that the action of a scalar function f , such as the step function, on a diagonalizable matrix $\mathbf{X} \equiv \mathbf{Y}\mathbf{\Lambda}\mathbf{Y}^{-1}$ can be expressed as

$$f(\mathbf{X}) = \mathbf{Y}f(\mathbf{\Lambda})\mathbf{Y}^{-1}$$

so we can write

$$\Theta(-\mathbf{N}\mathbf{M}) = \mathbf{Z} \begin{pmatrix} \Theta(-\Omega_+) & 0 \\ 0 & \Theta(\Omega_+) \end{pmatrix} \mathbf{Z}^{-1} = \mathbf{Z} \begin{pmatrix} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{1} \end{pmatrix} \mathbf{Z}^{-1} \quad (3.43)$$

and so it becomes clear that if we define $\tilde{\mathbf{M}} = \mathbf{M} + \eta\mathbf{N}\Theta(-\mathbf{N}\mathbf{M})$, we can write

$$\tilde{\mathbf{M}}\mathbf{Z} = \mathbf{M}\mathbf{Z} + \eta\mathbf{N}\Theta(-\mathbf{N}\mathbf{M})\mathbf{Z} = \mathbf{N}\mathbf{Z} \begin{pmatrix} \Omega_+ & 0 \\ 0 & -\Omega_+ \end{pmatrix} + \mathbf{N}\mathbf{Z} \begin{pmatrix} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \eta \end{pmatrix} \underbrace{\mathbf{Z}^{-1}\mathbf{Z}}_{\mathbf{1}} = \mathbf{N}\mathbf{Z} \begin{pmatrix} \Omega_+ & 0 \\ 0 & -\Omega_+ + \eta \end{pmatrix} \quad (3.44)$$

3.2.1 Trials of different combinations of the supermetric and the auxiliary block

It is understood that the notations $<, >$ and 2h1p, 2p1h can be used interchangeably, respectively. Tim's supermatrix is given by

$$\mathbf{H} = \begin{pmatrix} \mathbf{F} & \mathbf{V}^{2h1p} & \mathbf{V}^{2h1p} & \mathbf{V}^{2plh} & \mathbf{V}^{2plh} \\ (\mathbf{V}^{2h1p})^\dagger & & & & \\ (\mathbf{V}^{2h1p})^\dagger & \mathbf{C}^{2hlp} & & & \mathbf{0} \\ (\mathbf{V}^{2plh})^\dagger & & & & \\ (\mathbf{V}^{2plh})^\dagger & \mathbf{0} & & & \mathbf{C}^{2plh} \end{pmatrix} \quad (3.45)$$

We are told that $\mathbf{C}^{2hlp} = \varepsilon^{1h} \oplus (-\tilde{\mathbf{M}})$ and $\mathbf{C}^{2plh} = \varepsilon^{1p} \oplus \tilde{\mathbf{M}}$ and further, that the super-metric is

$$\mathcal{N} = \begin{pmatrix} \mathbf{1} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{1} \oplus \mathbf{N} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{1} \oplus \mathbf{N} \end{pmatrix} \quad (3.46)$$

But this doesn't seem to work so we will try out different combinations. Let's just focus on the 2h1p sector for now, so the Hamiltonian is given by

$$\mathbf{H}^{2\text{h1p}} = \begin{pmatrix} \mathbf{F}_{P,P} & \mathbf{V}_{P,O^2V}^{2\text{h1p}} & \mathbf{V}_{P,O^2V}^{2\text{h1p}} \\ \left(\mathbf{V}_{P,O^2V}^{2\text{h1p}}\right)^\dagger & & \\ \left(\mathbf{V}_{P,O^2V}^{2\text{h1p}}\right)^\dagger & \mathbf{C}_{2O^2V,2O^2V}^{2\text{h1p}} & \end{pmatrix} \quad (3.47)$$

Multiplication by the excitation vector

First, we can take

$$\mathbf{H}\mathbf{R} \quad (3.48)$$

$$= \begin{pmatrix} \mathbf{F}_{P,P} & \mathbf{V}_{P,O^2V}^{2\text{h1p}} & \mathbf{V}_{P,O^2V}^{2\text{h1p}} & \mathbf{V}_{P,OV^2}^{2\text{plh}} & \mathbf{V}_{P,OV^2}^{2\text{plh}} \\ \left(\mathbf{V}_{P,O^2V}^{2\text{h1p}}\right)^\dagger & & & & \\ \left(\mathbf{V}_{P,O^2V}^{2\text{h1p}}\right)^\dagger & \mathbf{C}_{2O^2V,2O^2V}^{2\text{h1p}} & & \mathbf{0} & \\ \left(\mathbf{V}_{P,OV^2}^{2\text{plh}}\right)^\dagger & & & & \\ \left(\mathbf{V}_{P,OV^2}^{2\text{plh}}\right)^\dagger & \mathbf{0} & & \mathbf{C}_{OV^2,OV^2}^{2\text{plh}} & \end{pmatrix} \begin{pmatrix} r_i \\ r_a \\ r_{i[jb]} \\ \bar{r}_{i[jb]} \\ r_{[jb]a} \\ \bar{r}_{[jb]a} \end{pmatrix} \quad (3.49)$$

$$= \begin{pmatrix} \begin{pmatrix} \mathbf{F}_{OO} & \mathbf{F}_{OV} \\ \mathbf{F}_{VO} & \mathbf{F}_{VV} \end{pmatrix}_{P,P} \begin{pmatrix} r_i \\ r_a \end{pmatrix}_{P,T} + \begin{pmatrix} \mathbf{V}_{O,i[jb]}^{2\text{h1p}} & \mathbf{V}_{O,i[jb]}^{2\text{h1p}} \\ \mathbf{V}_{V,i[jb]}^{2\text{h1p}} & \mathbf{V}_{V,i[jb]}^{2\text{h1p}} \end{pmatrix}_{P,2A} \begin{pmatrix} r_{i[jb]} \\ \bar{r}_{i[jb]} \end{pmatrix}_{2A,T} + \begin{pmatrix} \mathbf{V}_{O,[jb]a}^{2\text{plh}} & \mathbf{V}_{O,[jb]a}^{2\text{plh}} \\ \mathbf{V}_{V,[jb]a}^{2\text{plh}} & \mathbf{V}_{V,[jb]a}^{2\text{plh}} \end{pmatrix}_{P,2B} \begin{pmatrix} r_{[jb]a} \\ \bar{r}_{[jb]a} \end{pmatrix}_{2B,T} \\ \begin{pmatrix} \left(\mathbf{V}_{O,i[jb]}^{2\text{h1p}}\right)^\dagger & \left(\mathbf{V}_{V,i[jb]}^{2\text{h1p}}\right)^\dagger \\ \left(\mathbf{V}_{O,i[jb]}^{2\text{h1p}}\right)^\dagger & \left(\mathbf{V}_{V,i[jb]}^{2\text{h1p}}\right)^\dagger \end{pmatrix}_{2A,P} \begin{pmatrix} r_i \\ r_a \end{pmatrix}_{P,T} + \left[\epsilon_{O,O}^{1\text{h}} \otimes \mathbf{1}_{2OV,2OV} + \mathbf{1}_{O,O} \otimes -\tilde{\mathbf{M}}_{2OV,2OV}\right]_{2A,2A} \begin{pmatrix} r_{i[jb]} \\ \bar{r}_{i[jb]} \end{pmatrix}_{2A,T} \\ \begin{pmatrix} \left(\mathbf{V}_{O,[jb]a}^{2\text{plh}}\right)^\dagger & \left(\mathbf{V}_{V,[jb]a}^{2\text{plh}}\right)^\dagger \\ \left(\mathbf{V}_{O,[jb]a}^{2\text{plh}}\right)^\dagger & \left(\mathbf{V}_{V,[jb]a}^{2\text{plh}}\right)^\dagger \end{pmatrix}_{2B,P} \begin{pmatrix} r_i \\ r_a \end{pmatrix}_{P,T} + \left[\epsilon_{V,V}^{1\text{p}} \otimes \mathbf{1}_{2OV,2OV} + \mathbf{1}_{V,V} \otimes \tilde{\mathbf{M}}_{2OV,2OV}\right]_{2B,2B} \begin{pmatrix} r_{[jb]a} \\ \bar{r}_{[jb]a} \end{pmatrix}_{2B,T} \end{pmatrix} \quad (3.50)$$

$$= \begin{pmatrix} \mathbf{F}_{OO}\mathbf{r}_i + \mathbf{F}_{OV}\mathbf{r}_a + \mathbf{V}_{O,i[jb]}^{2\text{h1p}}\mathbf{r}_{i[jb]} + \mathbf{V}_{O,i[jb]}^{2\text{h1p}}\bar{\mathbf{r}}_{i[jb]} + \mathbf{V}_{O,[jb]a}^{2\text{plh}}\mathbf{r}_{[jb]a} + \mathbf{V}_{O,[jb]a}^{2\text{plh}}\bar{\mathbf{r}}_{[jb]a} \\ \mathbf{F}_{VO}\mathbf{r}_i + \mathbf{F}_{VV}\mathbf{r}_a + \mathbf{V}_{V,i[jb]}^{2\text{h1p}}\mathbf{r}_{i[jb]} + \mathbf{V}_{V,i[jb]}^{2\text{h1p}}\bar{\mathbf{r}}_{i[jb]} + \mathbf{V}_{V,[jb]a}^{2\text{plh}}\mathbf{r}_{[jb]a} + \mathbf{V}_{V,[jb]a}^{2\text{plh}}\bar{\mathbf{r}}_{[jb]a} \end{pmatrix}_{P+2A,T} \quad (3.51)$$

$$= \begin{pmatrix} \sum_j f_{ij} r_j + \sum_b f_{ib} r_b + \sum_{klc} \langle i c | k l \rangle r_{k[lc]} + \sum_{kcd} \langle i k | d c \rangle r_{[kc]d} + \sum_{klc} \langle i c | k l \rangle \bar{r}_{k[lc]} + \sum_{kcd} \langle i k | d c \rangle \bar{r}_{[kc]d} \\ \sum_j f_{aj} r_j + \sum_b f_{ab} r_b + \sum_{klc} \langle a c | k l \rangle r_{k[lc]} + \sum_{kcd} \langle a k | d c \rangle r_{[kc]d} + \sum_{klc} \langle a c | k l \rangle \bar{r}_{k[lc]} + \sum_{kcd} \langle a k | d c \rangle \bar{r}_{[kc]d} \end{pmatrix} \quad (3.52)$$

Just evaluate

$$\left[\epsilon_{O,O}^{1\text{ h}} \otimes \mathbf{1}_{2OV,2OV} + \mathbf{1}_{O,O} \otimes -\tilde{\mathbf{M}}_{2OV,2OV} \right]_{2A,2A} \begin{pmatrix} \mathbf{r}_{i[jb]} \\ \bar{\mathbf{r}}_{i[\bar{j}\bar{b}]} \end{pmatrix}_{2A,T} \quad (3.53)$$

$$= (\epsilon_{O,O}^{1\text{ h}} \otimes \mathbf{1}_{2OV,2OV}) \begin{pmatrix} \mathbf{r}_{i[jb]} \\ \bar{\mathbf{r}}_{i[\bar{j}\bar{b}]} \end{pmatrix}_{2A,T} - (\mathbf{1}_{O,O} \otimes \tilde{\mathbf{M}}_{2OV,2OV}) \begin{pmatrix} \mathbf{r}_{i[jb]} \\ \bar{\mathbf{r}}_{i[\bar{j}\bar{b}]} \end{pmatrix}_{2A,T} \quad (3.54)$$

$$(3.55)$$

For these, we can use the formula

$$(A \otimes B) K = \begin{bmatrix} \sum_{j=1}^n a_{1j} B K^{(j)} \\ \sum_{j=1}^n a_{2j} B K^{(j)} \\ \vdots \\ \sum_{j=1}^n a_{mj} B K^{(j)} \end{bmatrix} \quad (3.56)$$

with

$$\mathbf{K} = \begin{pmatrix} \mathbf{r}_{i[jb]} \\ \bar{\mathbf{r}}_{i[jb]} \end{pmatrix} = \begin{pmatrix} r_{1[jb]} \\ \bar{r}_{1[jb]} \\ r_{2[jb]} \\ \bar{r}_{2[jb]} \\ \vdots \\ r_{O[jb]} \\ \bar{r}_{O[jb]} \end{pmatrix} = \begin{pmatrix} K^{(1)} \\ K^{(2)} \\ \vdots \\ K^{(O)} \end{pmatrix} \in \mathbb{R}^{2O^2V}, \quad K^{(i)} = \begin{pmatrix} r_{i[jb]} \\ \bar{r}_{i[jb]} \end{pmatrix} \in \mathbb{R}^{2OV} \quad (3.57)$$

so we can see that

$$(\epsilon_{O,O}^{1\text{ h}} \otimes \mathbf{1}_{2OV,2OV})_{2A,2A} \begin{pmatrix} \mathbf{r}_{i[jb]} \\ \bar{\mathbf{r}}_{i[\bar{j}\bar{b}]} \end{pmatrix}_{2A,T} = \begin{pmatrix} \epsilon_{11}^{1h} K^{(1)} + \epsilon_{12}^{1h} K^{(2)} + \dots + \epsilon_{1O}^{1h} K^{(O)} \\ \epsilon_{21}^{1h} K^{(1)} + \epsilon_{22}^{1h} K^{(2)} + \dots + \epsilon_{2O}^{1h} K^{(O)} \\ \vdots \\ \epsilon_{O1}^{1h} K^{(1)} + \epsilon_{O2}^{1h} K^{(2)} + \dots + \epsilon_{OO}^{1h} K^{(O)} \end{pmatrix} \quad (3.58)$$

$$= \begin{pmatrix} \epsilon_{11}^{1h} K^{(1)} + \dots + 0 \\ 0 + \epsilon_{22}^{1h} K^{(2)} + \dots + 0 \\ \vdots \\ 0 + \dots + \epsilon_{OO}^{1h} K^{(O)} \end{pmatrix} = \begin{pmatrix} \epsilon_{11}^{1h} \begin{pmatrix} r_{1[jb]} \\ \bar{r}_{1[\bar{j}\bar{b}]} \end{pmatrix} \\ \epsilon_{22}^{1h} \begin{pmatrix} r_{2[jb]} \\ \bar{r}_{2[\bar{j}\bar{b}]} \end{pmatrix} \\ \vdots \\ \epsilon_{OO}^{1h} \begin{pmatrix} r_{O[jb]} \\ \bar{r}_{O[\bar{j}\bar{b}]} \end{pmatrix} \end{pmatrix} = \begin{pmatrix} \epsilon^{1h} \mathbf{r}_{i[jb]} \\ \epsilon^{1h} \bar{\mathbf{r}}_{i[\bar{j}\bar{b}]} \end{pmatrix} \quad (3.59)$$

Next, it is useful to define (where the composite index $\mu \equiv OV$)

$$\mathbf{K} = \begin{pmatrix} \mathbf{r}_{i[jb]} \\ \bar{\mathbf{r}}_{i[jb]} \end{pmatrix} = \begin{pmatrix} r_{i[\mu_1]} \\ \bar{r}_{i[\mu_2]} \\ r_{i[\mu_3]} \\ \bar{r}_{i[\mu_4]} \\ \vdots \\ r_{i[\mu_{2OV-1}]} \\ \bar{r}_{i[\mu_{2OV}]} \end{pmatrix} = \begin{pmatrix} K^{(1)} \\ K^{(2)} \\ \vdots \\ K^{(2OV)} \end{pmatrix} \in \mathbb{R}^{2O^2V}, \quad K^{(i)} = (r_{i[jb]}/\bar{r}_{i[jb]}) \in \mathbb{R}^O \quad (3.60)$$

and

$$\left(\mathbf{1}_{O,O} \otimes \tilde{\mathbf{M}}_{2OV,2OV} \right)_{2A,2A} \begin{pmatrix} \mathbf{r}_{i[jb]} \\ \bar{\mathbf{r}}_{i[jb]} \end{pmatrix}_{2A,T} = \left(\tilde{\mathbf{M}}_{2OV,2OV} \otimes \mathbf{1}_{O,O} \right)_{2A,2A} \begin{pmatrix} \mathbf{r}_{i[jb]} \\ \bar{\mathbf{r}}_{i[jb]} \end{pmatrix}_{2A,T} \quad (3.61)$$

$$= \begin{pmatrix} \tilde{\mathbf{M}}_{11} K^{(1)} + \dots + \tilde{\mathbf{M}}_{1,OV} K^{(OV)} + \tilde{\mathbf{M}}_{1,OV+1} K^{(OV+1)} + \dots + \tilde{\mathbf{M}}_{1,2OV} K^{(2OV)} \\ \tilde{\mathbf{M}}_{2,1} K^{(1)} + \dots + \tilde{\mathbf{M}}_{2,OV} K^{(OV)} + \tilde{\mathbf{M}}_{2,OV+1} K^{(OV+1)} + \dots + \tilde{\mathbf{M}}_{2,2OV} K^{(2OV)} \\ \vdots \\ \tilde{\mathbf{M}}_{OV,1} K^{(1)} + \dots + \tilde{\mathbf{M}}_{OV,OV} K^{(OV)} + \tilde{\mathbf{M}}_{OV,OV+1} K^{(OV+1)} + \dots + \tilde{\mathbf{M}}_{OV,2OV} K^{(2OV)} \\ \tilde{\mathbf{M}}_{OV+1,1} K^{(1)} + \dots + \tilde{\mathbf{M}}_{OV+1,OV} K^{(OV)} + \tilde{\mathbf{M}}_{OV+1,OV+1} K^{(OV+1)} + \dots + \tilde{\mathbf{M}}_{OV+1,2OV} K^{(2OV)} \\ \vdots \\ \tilde{\mathbf{M}}_{2OV,1} K^{(1)} + \dots + \tilde{\mathbf{M}}_{2OV,OV} K^{(OV)} + \tilde{\mathbf{M}}_{2OV,OV+1} K^{(OV+1)} + \dots + \tilde{\mathbf{M}}_{2OV,2OV} K^{(2OV)} \end{pmatrix} \quad (3.62)$$

$$= \begin{pmatrix} \tilde{\mathbf{M}}_{xx} K_{xx} + \tilde{\mathbf{M}}_{xd} K_{xd} \\ \tilde{\mathbf{M}}_{dx} K_{dx} + \tilde{\mathbf{M}}_{dd} K_{dd} \end{pmatrix} \quad (3.63)$$

Direct sum

The direct sum cannot work in neither the supermetric nor the auxiliary block because the shapes won't match. For example, we would be having $\mathbf{C}^{2\text{hlp}} = \varepsilon^{1\text{h}} \oplus_{\text{direct}} (-\tilde{\mathbf{M}})$ with the column dimension $O + 2OV$ which does not equal the width of its upstairs neighbor $(\mathbf{V}^{2\text{hlp}} \quad \mathbf{V}^{2\text{hlp}})$, which is $2O^2V$. The same kind of idea goes for the supermetric; $(\mathbf{V}^{2\text{hlp}} \quad \mathbf{V}^{2\text{hlp}})^\dagger$ will have row dimension $2O^2V$ and if $\mathcal{N} = \begin{pmatrix} \mathbf{1}_{P,P} & 0 \\ 0 & \mathbf{1}_{O,O} \oplus_{\text{direct}} \mathbf{N}_{2OV,2OV} \end{pmatrix}$, then the row dimension of the supermetric in the 2hlp space is $O + 2OV$ again.

Supermetric: Kronecker product, Auxiliary: Kronecker sum

Note that it makes the most sense for the auxiliary block to be a Kronecker sum, because this was the case for TDA as can be seen in 3.9. So here, I tried the case where the supermetric

is a Kronecker product

$$\mathcal{N}^{2\text{hlp}} = \begin{pmatrix} \mathbf{1}_{P,P} & 0 \\ 0 & \mathbf{1}_{O,O} \otimes \mathbf{N}_{2OV,2OV} \end{pmatrix} \quad (3.64)$$

and the auxiliary block is a Kronecker sum. Now we can consider the matrix multiplication

$$\mathcal{N}^{2\text{hlp}} \mathbf{H}^{2\text{hlp}} = \begin{pmatrix} \mathbf{1}_{P,P} & 0 \\ 0 & \mathbf{1}_{O,O} \otimes \mathbf{N}_{2OV,2OV} \end{pmatrix} \begin{pmatrix} \mathbf{F}_{P,P} & \mathbf{V}_{P,O^2V}^{2\text{hlp}} & \mathbf{V}_{P,O^2V}^{2\text{hlp}} \\ \left(\mathbf{V}_{P,O^2V}^{2\text{hlp}}\right)^\dagger & & \\ \left(\mathbf{V}_{P,O^2V}^{2\text{hlp}}\right)^\dagger & \mathbf{C}_{2O^2V,2O^2V}^{2\text{hlp}} & \end{pmatrix} \quad (3.65)$$

$$= \begin{pmatrix} \mathbf{F}_{P,P} & (\mathbf{V}^{2\text{hlp}} \ \mathbf{V}^{2\text{hlp}})_{P,2O^2V} \\ (\mathbf{1} \otimes \mathbf{N})_{2O^2V,2O^2V} \begin{pmatrix} (\mathbf{V}^{2\text{hlp}})^\dagger \\ (\mathbf{V}^{2\text{hlp}})^\dagger \end{pmatrix}_{2O^2V,P} & (\mathbf{1} \otimes \mathbf{N})_{2O^2V,2O^2V} \mathbf{C}_{2O^2V,2O^2V}^{2\text{hlp}} \end{pmatrix} \quad (3.66)$$

$$(3.67)$$

Evaluating the off-diagonal term, we have ($\mathbf{V}^{2\text{hlp}}$ has the elements $V_{p,k[ia]}^{2\text{hlp}} = \langle pa|ki \rangle \equiv (pk|ia)$ and $\mathbf{N}_{2OV,2OV} = \mathbf{1}_{OV,OV} \oplus_{\text{direct}} -\mathbf{1}_{OV,OV}$):

$$(\mathbf{1}_{O,O} \otimes \mathbf{N}_{2OV,2OV}) \begin{pmatrix} (\mathbf{V}^{2\text{hlp}})^\dagger \\ (\mathbf{V}^{2\text{hlp}})^\dagger \end{pmatrix}_{2O^2V,P} = \begin{pmatrix} (\mathbf{V}^{2\text{hlp}})^\dagger \\ -(\mathbf{V}^{2\text{hlp}})^\dagger \end{pmatrix}_{2O^2V,P} \quad (3.68)$$

Evaluating the auxiliary term with $\mathbf{C}_{2O^2V,2O^2V}^{2\text{hlp}} = \epsilon^{1\text{h}} \oplus_{\text{kron}} (-\tilde{\mathbf{M}}) = \epsilon_{O,O}^{1\text{h}} \otimes \mathbf{1}_{2OV,2OV} + \mathbf{1}_{O,O} \otimes (-\tilde{\mathbf{M}})_{2OV,2OV}$ we have

$$(\mathbf{1} \otimes \mathbf{N}) \mathbf{C}^{2\text{hlp}} = (\mathbf{1}_{O,O} \otimes \mathbf{N}_{2OV,2OV}) \left(\epsilon_{O,O}^{1\text{h}} \otimes \mathbf{1}_{2OV,2OV} + \mathbf{1}_{O,O} \otimes (-\tilde{\mathbf{M}})_{2OV,2OV} \right) \quad (3.69)$$

$$= \epsilon_{O,O}^{1\text{h}} \otimes \mathbf{N}_{2OV,2OV} + \mathbf{1}_{O,O} \otimes -\mathbf{N}_{2OV,2OV} \tilde{\mathbf{M}}_{2OV,2OV} \quad (3.70)$$

$$= [(\epsilon_{O,O}^{1\text{h}} \otimes \mathbf{1}_{OV,OV}) \oplus_{\text{direct}} -(\epsilon_{O,O}^{1\text{h}} \otimes \mathbf{1}_{OV,OV})] + (\mathbf{1}_{O,O} \otimes -\mathbf{N}_{2OV,2OV} \tilde{\mathbf{M}}_{2OV,2OV}) \quad (3.71)$$

$$= \begin{pmatrix} \epsilon^{1\text{h}} \otimes \mathbf{1} & \mathbf{0} \\ \mathbf{0} & -(\epsilon^{1\text{h}} \otimes \mathbf{1}) \end{pmatrix}_{2O^2V} + \left(\mathbf{1}_O \otimes -\mathbf{Z}_{2OV} \begin{pmatrix} \Omega & \mathbf{0} \\ \mathbf{0} & \eta - \Omega \end{pmatrix}_{2OV} \mathbf{Z}_{2OV}^{-1} \right)_{2O^2V} \quad (3.72)$$

$$= \begin{pmatrix} \epsilon^{1\text{h}} \otimes \mathbf{1} & \mathbf{0} \\ \mathbf{0} & -(\epsilon^{1\text{h}} \otimes \mathbf{1}) \end{pmatrix}_{2O^2V} - \left[(\mathbf{1} \otimes \mathbf{Z}) \begin{pmatrix} \mathbf{1} \otimes \Omega & \mathbf{0} \\ \mathbf{0} & \mathbf{1} \otimes (\eta - \Omega) \end{pmatrix} (\mathbf{1} \otimes \mathbf{Z}^{-1}) \right]_{2O^2V} \quad (3.73)$$

$$= (\mathbf{1} \otimes \mathbf{Z}) \begin{pmatrix} \epsilon^{1\text{h}} \otimes \mathbf{1} + \mathbf{1} \otimes -\Omega & \mathbf{0} \\ \mathbf{0} & -(\epsilon^{1\text{h}} \otimes \mathbf{1}) - (\mathbf{1} \otimes (\eta - \Omega)) \end{pmatrix} (\mathbf{1} \otimes \mathbf{Z}^{-1}) \quad (3.74)$$

$$(3.75)$$

where $\mathbf{Z} = \begin{pmatrix} \mathbf{X} & \mathbf{Y} \\ \mathbf{Y} & \mathbf{X} \end{pmatrix}$ is the eigenvector matrix and Ω is the diagonal matrix of positive excitation energies.

Similarity transformation

Now let us define the rotation $\zeta = \begin{pmatrix} \mathbf{1} & 0 \\ 0 & \mathbf{1} \otimes \mathbf{Z} \end{pmatrix}$. We can left multiply by ζ^{-1} and right multiply by ζ to get

$$\zeta^{-1} \mathcal{N}^{2\text{hlp}} \mathbf{H}^{2\text{hlp}} \zeta = \begin{pmatrix} \mathbf{1} & 0 \\ 0 & \mathbf{1} \otimes \mathbf{Z}^{-1} \end{pmatrix} \begin{pmatrix} \mathbf{F} & (\mathbf{V}^{2\text{hlp}} \ \mathbf{V}^{2\text{hlp}}) \\ \begin{pmatrix} (\mathbf{V}^{2\text{hlp}})^\dagger \\ -(\mathbf{V}^{2\text{hlp}})^\dagger \end{pmatrix} & (\mathbf{1} \otimes \mathbf{N}) \mathbf{C}^{2\text{hlp}} \end{pmatrix} \begin{pmatrix} \mathbf{1} & 0 \\ 0 & \mathbf{1} \otimes \mathbf{Z} \end{pmatrix} \quad (3.76)$$

$$= \begin{pmatrix} \mathbf{F} & (\mathbf{V}^{2\text{hlp}} \ \mathbf{V}^{2\text{hlp}}) (\mathbf{1} \otimes \mathbf{Z}) \\ (\mathbf{1} \otimes \mathbf{Z}^{-1}) \begin{pmatrix} (\mathbf{V}^{2\text{hlp}})^\dagger \\ -(\mathbf{V}^{2\text{hlp}})^\dagger \end{pmatrix} & (\mathbf{1} \otimes \mathbf{Z}^{-1} \mathbf{Z}) \begin{pmatrix} \epsilon^{1 \text{ h}} \oplus_{\text{kron}} -\Omega & \mathbf{0} \\ \mathbf{0} & -\epsilon^{1 \text{ h}} \oplus_{\text{kron}} [\eta - \Omega] \end{pmatrix} (\mathbf{1} \otimes \mathbf{Z}^{-1} \mathbf{Z}) \end{pmatrix} \quad (3.77)$$

$$= \begin{pmatrix} \mathbf{F} & (\mathbf{V}^{2\text{hlp}} \ \mathbf{V}^{2\text{hlp}}) \left(\mathbf{1} \otimes \begin{pmatrix} \mathbf{X} & \mathbf{Y} \\ \mathbf{Y} & \mathbf{X} \end{pmatrix} \right) \\ \left(\mathbf{1} \otimes \begin{pmatrix} \mathbf{X} & \mathbf{Y} \\ \mathbf{Y} & \mathbf{X} \end{pmatrix}^{-1} \right) (\mathbf{1} \otimes \mathbf{N}) \begin{pmatrix} (\mathbf{V}^{2\text{hlp}})^\dagger \\ (\mathbf{V}^{2\text{hlp}})^\dagger \end{pmatrix} & \begin{pmatrix} \epsilon^{1 \text{ h}} \oplus_{\text{kron}} -\Omega & \mathbf{0} \\ \mathbf{0} & -\epsilon^{1 \text{ h}} \oplus_{\text{kron}} [\eta - \Omega] \end{pmatrix} \end{pmatrix} \quad (3.78)$$

$$= \begin{pmatrix} \mathbf{F} & (\mathbf{V}^{2\text{hlp}} (\mathbf{X} + \mathbf{Y}) \ \mathbf{V}^{2\text{hlp}} (\mathbf{X} + \mathbf{Y})) \\ \left(\mathbf{1} \otimes \begin{pmatrix} \mathbf{X} & \mathbf{Y} \\ \mathbf{Y} & \mathbf{X} \end{pmatrix}^{-1} \right) \begin{pmatrix} (\mathbf{V}^{2\text{hlp}})^\dagger \\ -(\mathbf{V}^{2\text{hlp}})^\dagger \end{pmatrix} & \begin{pmatrix} \epsilon^{1 \text{ h}} \oplus_{\text{kron}} -\Omega & \mathbf{0} \\ \mathbf{0} & -\epsilon^{1 \text{ h}} \oplus_{\text{kron}} [\eta - \Omega] \end{pmatrix} \end{pmatrix} \quad (3.79)$$

But because it is true that \mathbf{Z} are the eigenvectors of a non-Hermitian eigenproblem, it is not true that $\mathbf{Z}^{-1} = \mathbf{Z}^\dagger$, so we cannot simplify the lower left block any further. Accordingly, doing ED of this form for the supermatrices gives the wrong spectrum, but I have included this derivation of the similarity transformation because it seems like the most promising approach I have considered so far.

Supermetric: Kronecker sum, Auxiliary: Kronecker sum

Now we can consider the matrix multiplication

$$\mathcal{N}^{2\text{hlp}} \mathbf{H}^{2\text{hlp}} = \begin{pmatrix} \mathbf{1}_{P,P} & 0 \\ 0 & \mathbf{1}_{O,O} \oplus_{\text{kron}} \mathbf{N}_{2OV,2OV} \end{pmatrix} \begin{pmatrix} \mathbf{F}_{P,P} & \mathbf{V}_{P,O^2V}^{2\text{hlp}} \ \mathbf{V}_{P,O^2V}^{2\text{hlp}} \\ \begin{pmatrix} (\mathbf{V}_{P,O^2V}^{2\text{hlp}})^\dagger \\ (\mathbf{V}_{P,O^2V}^{2\text{hlp}})^\dagger \end{pmatrix} & \mathbf{C}_{2O^2V,2O^2V}^{2\text{hlp}} \end{pmatrix} \quad (3.80)$$

$$= \begin{pmatrix} \mathbf{F}_{P,P} & (\mathbf{V}^{2\text{hlp}} \ \mathbf{V}^{2\text{hlp}})_{P,2O^2V} \\ (\mathbf{1} \oplus_{\text{kron}} \mathbf{N})_{2O^2V,2O^2V} \begin{pmatrix} (\mathbf{V}^{2\text{hlp}})^\dagger \\ (\mathbf{V}^{2\text{hlp}})^\dagger \end{pmatrix}_{2O^2V,P} & (\mathbf{1} \oplus_{\text{kron}} \mathbf{N})_{2O^2V,2O^2V} \mathbf{C}_{2O^2V,2O^2V}^{2\text{hlp}} \end{pmatrix} \quad (3.81)$$

$$(3.82)$$

First, we can consider the off diagonal term

$$(\mathbf{1} \oplus_{\text{kron}} \mathbf{N}_{2OV,2OV}) \begin{pmatrix} (\mathbf{V}^{2h1p})^\dagger \\ (\mathbf{V}^{2h1p})^\dagger \end{pmatrix}_{2O^2V,P} = (\mathbf{1}_O \otimes \mathbf{1}_{2OV} + \mathbf{1}_O \otimes \mathbf{N}_{2OV}) \begin{pmatrix} (\mathbf{V}^{2h1p})^\dagger \\ (\mathbf{V}^{2h1p})^\dagger \end{pmatrix}_{2O^2V,P} \quad (3.83)$$

$$= \begin{pmatrix} (\mathbf{V}^{2h1p})^\dagger \\ (\mathbf{V}^{2h1p})^\dagger \end{pmatrix}_{2O^2V,P} + \begin{pmatrix} (\mathbf{V}^{2h1p})^\dagger \\ -(\mathbf{V}^{2h1p})^\dagger \end{pmatrix}_{2O^2V,P} \quad (3.84)$$

$$= \begin{pmatrix} 2(\mathbf{V}^{2h1p})^\dagger \\ 0 \end{pmatrix}_{2O^2V,P} \quad (3.85)$$

Next, we can consider the auxiliary block

$$(\mathbf{1} \oplus_{\text{kron}} \mathbf{N}) \mathbf{C}^{2hlp} = (\mathbf{1}_{O,O} \oplus_{\text{kron}} \mathbf{N}_{2OV,2OV}) \left(\epsilon_{O,O}^{1\ h} \oplus_{\text{kron}} (-\tilde{\mathbf{M}})_{2OV,2OV} \right) \quad (3.86)$$

$$= (\mathbf{1}_O \otimes \mathbf{1}_{2OV} + \mathbf{1}_O \otimes \mathbf{N}_{2OV}) \left(\epsilon_{O,O}^{1\ h} \otimes \mathbf{1}_{2OV} + \mathbf{1}_O \otimes (-\tilde{\mathbf{M}})_{2OV} \right) \quad (3.87)$$

$$= \epsilon^{1\ h} \otimes \mathbf{1} + \mathbf{1} \otimes -\tilde{\mathbf{M}} + \epsilon^{1\ h} \otimes \mathbf{N} + \mathbf{1} \otimes -\mathbf{N}\tilde{\mathbf{M}} \quad (3.88)$$

$$= (\mathbf{1} \otimes (\mathbf{1} + \mathbf{N})) \left(\epsilon^{1\ h} \otimes \mathbf{1} + \mathbf{1} \otimes -\tilde{\mathbf{M}} \right) \quad (3.89)$$

$$(3.90)$$

Supermetric: Kronecker sum, Auxiliary: Kronecker product

Let us try the alternate case where $\mathbf{C}^{2hlp} = \left(\epsilon^{1\ h} \otimes -\tilde{\mathbf{M}} \right)$, which gives

$$(\mathbf{1} \oplus_{\text{kron}} \mathbf{N}) \mathbf{C}^{2hlp} = (\mathbf{1}_{O,O} \oplus_{\text{kron}} \mathbf{N}_{2OV,2OV}) \left(\epsilon_{O,O}^{1\ h} \otimes (-\tilde{\mathbf{M}})_{2OV,2OV} \right) \quad (3.91)$$

$$= (\mathbf{1}_O \otimes \mathbf{1}_{2OV} + \mathbf{1}_O \otimes \mathbf{N}_{2OV}) \left(\epsilon_{O,O}^{1\ h} \otimes (-\tilde{\mathbf{M}})_{2OV} \right) \quad (3.92)$$

$$= \epsilon^{1\ h} \otimes -\tilde{\mathbf{M}} + \epsilon^{1\ h} \otimes -\mathbf{N}\tilde{\mathbf{M}} \quad (3.93)$$

$$(3.94)$$

This is not what we want and the form for the off-diagonal term is the same as in the previous subsection.

3.2.2 Reverse engineering

We have the problem $\sigma = \mathcal{N}HR$. I know that σ is given by

$$\sigma_i = \sum_j f_{ij} r_j + \sum_b f_{ib} r_b + \sum_{klc} \langle i c | k l \rangle r_{k[lc]} + \sum_{kcd} \langle i k | d c \rangle r_{[kc]d} + \sum_{klc} \langle i c | k l \rangle \bar{r}_{k[lc]} + \sum_{kcd} \langle i k | d c \rangle \bar{r}_{[kc]d} \quad (3.95)$$

$$\sigma_a = \sum_j f_{aj} r_j + \sum_b f_{ab} r_b + \sum_{klc} \langle a c | k l \rangle r_{k[lc]} + \sum_{kcd} \langle a k | d c \rangle r_{[kc]d} + \sum_{klc} \langle a c | k l \rangle \bar{r}_{k[lc]} + \sum_{kcd} \langle a k | d c \rangle \bar{r}_{[kc]d} \quad (3.96)$$

$$\sigma_{i[ja]} = \sum_k \langle k a | i j \rangle r_k + \sum_b \langle b a | i j \rangle r_b + \varepsilon_i r_{i[ja]} - \sum_{kb} [\tilde{\mathbf{N}}\tilde{\mathbf{M}}]_{j a k b}^{\text{xx}} r_{i[kb]} - \sum_{kb} [\tilde{\mathbf{N}}\tilde{\mathbf{M}}]_{j a k b}^{\text{xd}} \bar{r}_{i[kb]} \quad (3.97)$$

$$\bar{\sigma}_{i[ja]} = - \sum_k \langle k a | i j \rangle r_k - \sum_b \langle b a | i j \rangle r_b + \varepsilon_i \bar{r}_{i[ja]} - \sum_{kb} [\tilde{\mathbf{N}}\tilde{\mathbf{M}}]_{j a, kb}^{\text{dx}} r_{i[kb]} - \sum_{kb} [\tilde{\mathbf{N}}\tilde{\mathbf{M}}]_{j a, kb}^{\text{dd}} \bar{r}_{i[kb]} \quad (3.98)$$

$$\sigma_{[ia]b} = \sum_j \langle j i | b a \rangle r_j + \sum_c \langle c i | b a \rangle r_c + \varepsilon_b r_{[ia]b} + \sum_{jc} [\tilde{\mathbf{N}}\tilde{\mathbf{M}}]_{ia, jc}^{\text{xx}} r_{[jc]b} + \sum_{jc} [\tilde{\mathbf{N}}\tilde{\mathbf{M}}]_{ia, jc}^{\text{xd}} \bar{r}_{[jc]b} \quad (3.99)$$

$$\bar{\sigma}_{[ia]b} = - \sum_j \langle j i | b a \rangle r_j - \sum_c \langle c i | b a \rangle r_c + \varepsilon_b \bar{r}_{[ia]b} + \sum_{jc} [\tilde{\mathbf{N}}\tilde{\mathbf{M}}]_{ia, jc}^{\text{dx}} r_{[jc]b} + \sum_{jc} [\tilde{\mathbf{N}}\tilde{\mathbf{M}}]_{ia, jc}^{\text{dd}} \bar{r}_{[jc]b} \quad (3.100)$$

$\mathbf{R}^{2h1p} = \begin{pmatrix} r_i \\ r_a \\ r_{i[jb]} \\ \bar{r}_{i[jb]} \end{pmatrix}$ is the excitation vector. We will assume the form $\mathcal{N}^{2h1p} = \begin{pmatrix} \mathbf{1} & 0 \\ 0 & \mathbf{X} \end{pmatrix}$. We assume that \mathbf{H}^{2h1p} is given by

$$\mathbf{H}^{2h1p} = \begin{pmatrix} \mathbf{F} & \mathbf{V}^{2h1p} & \mathbf{V}^{2h1p} \\ (\mathbf{V}^{2h1p})^\dagger & & \\ (\mathbf{V}^{2h1p})^\dagger & & \mathbf{C}^{2hlp} \end{pmatrix} \quad (3.101)$$

In our notation, $P = O + V$ is the number of molecular orbitals, $A = O^2V$ and T is the column dimension of our excitation vector.

$$\mathcal{N}^{2h1p} \mathbf{H}^{2h1p} \mathbf{R}^{2h1p} \quad (3.102)$$

$$= \begin{pmatrix} \mathbf{1}_{P,P} & 0 \\ 0 & \mathbf{X}_{2A,2A} \end{pmatrix}_{P+2A,P+2A} \begin{pmatrix} \mathbf{F}_{P,P} & \mathbf{V}_{P,A}^{2h1p} & \mathbf{V}_{P,A}^{2h1p} \\ (\mathbf{V}_{O,i[jb]}^{2h1p})^\dagger_{A,P} & & \\ (\mathbf{V}_{V,i[jb]}^{2h1p})^\dagger_{A,P} & \mathbf{C}_{2A,2A}^{2hlp} & \end{pmatrix}_{P+2A,P+2A} \begin{pmatrix} \mathbf{r}_i \\ \mathbf{r}_a \\ \mathbf{r}_{i[jb]} \\ \bar{\mathbf{r}}_{i[\bar{j}b]} \end{pmatrix}_{P+2A,T} \quad (3.103)$$

$$= \begin{pmatrix} \mathbf{1}_{P,P} \begin{pmatrix} \mathbf{F}_{OO} & \mathbf{F}_{OV} \\ \mathbf{F}_{VO} & \mathbf{F}_{VV} \end{pmatrix}_{P,P} \begin{pmatrix} \mathbf{r}_i \\ \mathbf{r}_a \end{pmatrix}_{P,T} + \mathbf{1}_{P,P} \begin{pmatrix} \mathbf{V}_{O,i[jb]}^{2h1p} & \mathbf{V}_{O,i[jb]}^{2h1p} \\ \mathbf{V}_{V,i[jb]}^{2h1p} & \mathbf{V}_{V,i[jb]}^{2h1p} \end{pmatrix}_{P,2A} \begin{pmatrix} \mathbf{r}_{i[jb]} \\ \bar{\mathbf{r}}_{i[\bar{j}b]} \end{pmatrix}_{2A,T} \\ \mathbf{X}_{2A,2A} \begin{pmatrix} (\mathbf{V}_{O,i[jb]}^{2h1p})^\dagger & (\mathbf{V}_{V,i[jb]}^{2h1p})^\dagger \\ (\mathbf{V}_{O,i[jb]}^{2h1p})^\dagger & (\mathbf{V}_{V,i[jb]}^{2h1p})^\dagger \end{pmatrix}_{2A,P} \begin{pmatrix} \mathbf{r}_i \\ \mathbf{r}_a \end{pmatrix}_{P,T} + \mathbf{X}_{2A,2A} \mathbf{C}_{2A,2A}^{2hlp} \begin{pmatrix} \mathbf{r}_{i[jb]} \\ \bar{\mathbf{r}}_{i[\bar{j}b]} \end{pmatrix}_{2A,T} \end{pmatrix} \quad (3.104)$$

$$= \begin{pmatrix} \mathbf{F}_{OO}\mathbf{r}_i + \mathbf{F}_{OV}\mathbf{r}_a + \mathbf{V}_{O,i[jb]}^{2h1p}\mathbf{r}_{i[jb]} + \mathbf{V}_{O,i[jb]}^{2h1p}\bar{\mathbf{r}}_{i[\bar{j}b]} \\ \mathbf{F}_{VO}\mathbf{r}_i + \mathbf{F}_{VV}\mathbf{r}_a + \mathbf{V}_{V,i[jb]}^{2h1p}\mathbf{r}_{i[jb]} + \mathbf{V}_{V,i[jb]}^{2h1p}\bar{\mathbf{r}}_{i[\bar{j}b]} \\ ? \end{pmatrix}_{P+2A,T} \quad (3.105)$$

$$= \begin{pmatrix} \sum_j f_{ij}r_j + \sum_b f_{ib}r_b + \sum_{klc} \langle i|c|k|l \rangle r_{k[lc]} + \sum_{klc} \langle i|c|k|l \rangle \bar{r}_{k[lc]} \\ \sum_j f_{aj}r_j + \sum_b f_{ab}r_b + \sum_{klc} \langle a|c|k|l \rangle r_{k[lc]} + \sum_{klc} \langle a|c|k|l \rangle \bar{r}_{k[lc]} \\ ? \end{pmatrix} \quad (3.106)$$

$$(3.107)$$

Now let's consider that $\mathbf{X}_{2A,2A} = \mathbf{1}_O \otimes \mathbf{N}_{2OV,2OV} = \mathbf{1}_O \otimes \begin{pmatrix} \mathbf{1}_{OV,OV} & 0 \\ 0 & -\mathbf{1}_{OV,OV} \end{pmatrix}$. Then, it becomes true that

$$(\mathbf{1}_O \otimes \mathbf{N}_{2OV,2OV}) \begin{pmatrix} (\mathbf{V}_{O,i[jb]}^{2h1p})^\dagger & (\mathbf{V}_{V,i[jb]}^{2h1p})^\dagger \\ (\mathbf{V}_{O,i[jb]}^{2h1p})^\dagger & (\mathbf{V}_{V,i[jb]}^{2h1p})^\dagger \end{pmatrix}_{2A,P} \begin{pmatrix} \mathbf{r}_i \\ \mathbf{r}_a \end{pmatrix}_{P,T} \quad (3.108)$$

$$= \begin{pmatrix} (\mathbf{V}_{O,i[jb]}^{2h1p})^\dagger & (\mathbf{V}_{V,i[jb]}^{2h1p})^\dagger \\ (-\mathbf{V}_{O,i[jb]}^{2h1p})^\dagger & -(\mathbf{V}_{V,i[jb]}^{2h1p})^\dagger \end{pmatrix}_{2A,P} \begin{pmatrix} \mathbf{r}_i \\ \mathbf{r}_a \end{pmatrix}_{P,T} \quad (3.109)$$

$$= \begin{pmatrix} \sum_k \langle k|a|i|j \rangle r_k + \sum_b \langle b|a|i|j \rangle r_b \\ -\sum_k \langle k|a|i|j \rangle r_k - \sum_b \langle b|a|i|j \rangle r_b \end{pmatrix}_{2A,T} \quad (3.110)$$

But it is still unclear how terms like 3.97, arising from the auxiliary space, come about.

It is unclear where these equations come from

I found that these equations give rise to nearly the same spectrum (test on LiH with cc-pvdz basis show up to $10^{-9}Ha$ of agreement) as that of the exact upfolded GW Hamiltonian (Booth's ED), which is given by

$$\mathbf{H}_{\text{Upfolded}}^{G_0W_0} = \begin{pmatrix} \mathbf{F} & \mathbf{W}^< & \mathbf{W}^> \\ \mathbf{W}^{<,\dagger} & \mathbf{d}^< & 0 \\ \mathbf{W}^{>,\dagger} & 0 & \mathbf{d}^> \end{pmatrix} \quad (3.111)$$

where we have the definitions

$$W_{pkv}^{< >} = (\epsilon_k + \Omega_v) \delta_{k,l} \delta_{v,v'} \quad (3.112)$$

It concerns me that the agreement isn't exact (below $10^{-13}Ha$). I would want to have this cleared up before I try to reduce the scaling by implementing the Arnoldi procedure they try. Also, I am not able to figure out what motivated the form for this upfolded Hamiltonian for Tim's GW -RPA. Specifically, if one interprets the \oplus as a direct sum, then the shapes of the matrices are not compatible since, for example, $\mathbf{C}^{2\text{hlp}} = \epsilon^{1\text{h}} \oplus (-\tilde{\mathbf{M}})$ has the column dimension $O + 2OV$ which does not equal the width of its upstairs neighbor $(\mathbf{V}^{2\text{hlp}} \quad \mathbf{V}^{2\text{hlp}})$, which is $2O^2V$. If one interprets the \oplus as a Kronecker sum, the shapes are compatible, but the energies are wrong. If we assume that the \oplus should actually be the Kronecker product \otimes , again the shapes will be compatible, but the energies are wrong. I asked Jinghong, Nemo, and Hamlin and no one was able to figure it out. Can I email Tim to ask him about this?

3.2.3 Krylov procedure to approximate the step function

It does not seem like a good idea to me to start applying the Krylov procedure without first having ED. But we can start to think about what this would look like. The matrix vector products contain terms like $\sum_{jc} [\tilde{\mathbf{N}}\tilde{\mathbf{M}}]_{ia,jc}^{\text{dd}} \bar{r}_{[jc]b}$. Right now, I am explicitly constructing $\Theta(-\mathbf{N}\tilde{\mathbf{M}})$, which requires diagonalizing $\mathbf{N}\tilde{\mathbf{M}}$, naively scaling as $O(N^6)$. Using a Krylov subspace method, we can avoid this. The idea is to approximate the entirety of $\mathbf{N}\tilde{\mathbf{M}}$ once before the start of the Davidson iteration, and then we can extract the xx, xd, dx, and dd blocks from the approximate matrix. Specifically

$$\mathbf{N}\tilde{\mathbf{M}} = \mathbf{N}(\mathbf{M} + \eta\mathbf{N}\Theta(-\mathbf{N}\tilde{\mathbf{M}})) = \mathbf{N}\mathbf{M} + \eta\Theta(-\mathbf{N}\tilde{\mathbf{M}}) \quad (3.113)$$

The first term is not a problem, but then we approximate the spectrum of $-\mathbf{N}\tilde{\mathbf{M}}$ using a Krylov subspace method, to determine where are the negative eigenvalues, thus determining the step function $\Theta(-\mathbf{N}\tilde{\mathbf{M}})$.

Arnoldi iteration

They suggest an Arnoldi procedure to determine the spectrum of $-\mathbf{N}\tilde{\mathbf{M}}$, since it is not Hermitian. We might be able to do better by converting into a symmetric problem.

Lanczos iteration

We start by considering $\mathbf{B} = \mathbf{N}\mathbf{M}\mathbf{N}$, which is symmetric since \mathbf{N} is symmetric and \mathbf{M} is symmetric. Then, we can do Lanczos to determine the spectrum of \mathbf{B} , giving the Ritz pairs $\{\lambda_i, \mathbf{v}_i\}$. Then, we can determine the step function on the \mathbf{B} space as $\mathbf{Q}\mathbf{V}_-\mathbf{V}_-^\dagger\mathbf{Q}^\dagger$, where \mathbf{V}_- is the matrix of Ritz vectors with negative Ritz values and \mathbf{Q} is the Krylov subspace. Then, we can transform back to the original space using \mathbf{N} , giving us $\Theta(-\mathbf{N}\mathbf{M}) = \mathbf{N}\mathbf{Q}\mathbf{V}_-\mathbf{V}_-^\dagger\mathbf{Q}^\dagger\mathbf{N}$.

I run into trouble when I try to do this because the spectrum of \mathbf{B} is completely positive, so it no longer makes sense to use the step function.

3.2.4 Tried and failed using Z-vector trick for dRPA

The super matrix that downfolds into the GW self-energy is

$$\begin{pmatrix} \mathbf{F} & \mathbf{V}^{2\text{h1p}} & \mathbf{V}^{2\text{p1 h}} \\ (\mathbf{V}^{2\text{ h1p}})^\dagger & \mathbf{C}^{2\text{hlp}} & \mathbf{0} \\ (\mathbf{V}^{2\text{plh}})^\dagger & \mathbf{0} & \mathbf{C}^{2\text{plh}} \end{pmatrix} \quad (3.114)$$

For dRPA, we will choose

$$\mathbf{C}^{2\text{hlp}} = \epsilon^{1\text{ h}} \oplus (-\mathbf{M}^{1/2}) \implies C_{i[ja],k[lc]}^{2\text{ h1p}} = [\epsilon_i - \mathbf{M}_{ja,lc}^{1/2}] \delta_{ik} \quad (3.115)$$

where \mathbf{M} is the matrix defined in (3.117). If we choose our unitary transformation to be $\mathbf{U}' = \mathbf{1} \oplus_{\text{diag}} (\mathbf{1} \otimes \mathbf{T})$, where \mathbf{T} is the matrix of eigenvectors of the symmetric formulation as

$$\mathbf{M}\mathbf{T} = \lambda\mathbf{T} \quad (3.116)$$

with the matrix \mathbf{M} defined as

$$\mathbf{M} = (\mathbf{A} - \mathbf{B})^{1/2}(\mathbf{A} + \mathbf{B})(\mathbf{A} - \mathbf{B})^{1/2} \quad (3.117)$$

with the identities $\lambda = \Omega^2$ and $\mathbf{T} = \Omega^{1/2} [\mathbf{A} - \mathbf{B}]^{-1/2} (\mathbf{X} + \mathbf{Y})$, where \mathbf{X} and \mathbf{Y} are the excitation and de-excitation vectors, respectively.

Exercise

Casida transformation

The matrix problem is:

$$\begin{bmatrix} \mathbf{A} & \mathbf{B} \\ -\mathbf{B} & -\mathbf{A} \end{bmatrix} \begin{bmatrix} \mathbf{X} & \mathbf{Y} \\ \mathbf{Y} & \mathbf{X} \end{bmatrix} = \begin{bmatrix} \mathbf{X} & \mathbf{Y} \\ \mathbf{Y} & \mathbf{X} \end{bmatrix} \begin{bmatrix} \Omega & 0 \\ 0 & -\Omega \end{bmatrix}. \quad (3.118)$$

which becomes equivalent to the pair of linear equations for each excitation mode

$$\begin{aligned} (\mathbf{A} + \mathbf{B})(X + Y)_\nu &= \Omega_\nu (X - Y)_\nu \\ (\mathbf{A} - \mathbf{B})(X - Y)_\nu &= \Omega_\nu (X + Y)_\nu \end{aligned} \quad (3.119)$$

We know we have the symmetric eigenproblem $\mathbf{M}T_\nu = \lambda_\nu T_\nu$, where $\mathbf{M} = (\mathbf{A} - \mathbf{B})^{1/2}(\mathbf{A} + \mathbf{B})(\mathbf{A} - \mathbf{B})^{1/2}$. Let us make the ansatz

$$\begin{aligned} (X + Y)_\nu &= \Omega_\nu^{-\frac{1}{2}} (\mathbf{A} - \mathbf{B})^{\frac{1}{2}} T_\nu \\ (X - Y)_\nu &= \Omega_\nu^{\frac{1}{2}} (\mathbf{A} - \mathbf{B})^{-\frac{1}{2}} T_\nu \end{aligned} \quad (3.120)$$

We know that this satisfies the biorthogonality relation since

$$(X + Y)_\nu^\dagger (X - Y)_\nu = \left(\Omega_\nu^{-\frac{1}{2}} (\mathbf{A} - \mathbf{B})^{\frac{1}{2}} T_\nu \right)^\dagger \left(\Omega_\nu^{\frac{1}{2}} (\mathbf{A} - \mathbf{B})^{-\frac{1}{2}} T_\nu \right) = T_\nu^\dagger T_\nu = 1 \quad (3.121)$$

Now, we can plug the ansatz 3.120 into the equations 3.119 to get

$$\begin{aligned} (\mathbf{A} + \mathbf{B}) \left(\Omega_\nu^{-\frac{1}{2}} (\mathbf{A} - \mathbf{B})^{\frac{1}{2}} T_\nu \right) &= \Omega_\nu \left(\Omega_\nu^{\frac{1}{2}} (\mathbf{A} - \mathbf{B})^{-\frac{1}{2}} T_\nu \right) \\ \implies \Omega_\nu^{-\frac{1}{2}} (\mathbf{A} + \mathbf{B}) (\mathbf{A} - \mathbf{B})^{\frac{1}{2}} T_\nu &= \Omega_\nu^{\frac{3}{2}} (\mathbf{A} - \mathbf{B})^{-\frac{1}{2}} T_\nu \\ \implies (\mathbf{A} - \mathbf{B})^{\frac{1}{2}} (\mathbf{A} + \mathbf{B}) (\mathbf{A} - \mathbf{B})^{\frac{1}{2}} T_\nu &= \Omega_\nu^2 T_\nu \end{aligned} \quad (3.122)$$

We make the ansatz that the eigenvectors of the symmetric formulation are given by $\mathbf{T} = \Omega^{\frac{1}{2}} (\mathbf{A} - \mathbf{B})^{-\frac{1}{2}} (\mathbf{X} + \mathbf{Y})$. Plugging into ?? gives us

$$(\mathbf{A} + \mathbf{B}) \left(\Omega^{-\frac{1}{2}} (\mathbf{A} - \mathbf{B})^{\frac{1}{2}} \mathbf{T} \right) = \Omega (\mathbf{X} - \mathbf{Y}) \quad (3.123)$$

$$\Omega^{-\frac{1}{2}} (\mathbf{A} + \mathbf{B}) (\mathbf{A} - \mathbf{B})^{\frac{1}{2}} \mathbf{T} = \Omega (\mathbf{X} - \mathbf{Y}) \quad (3.124)$$

$$\Omega^{-\frac{1}{2}} (\mathbf{A} - \mathbf{B})^{-\frac{1}{2}} \mathbf{M} \mathbf{T} = \Omega (\mathbf{X} - \mathbf{Y}) \quad (3.125)$$

$$(3.126)$$

Then, we can apply the unitary transformation to the Hamiltonian in Tim's formulation

as

$$\mathbf{H}' = \mathbf{U}'^\dagger \mathbf{H} \mathbf{U}' = \begin{pmatrix} \mathbf{1} & \mathbf{0} \\ \mathbf{0} & \mathbf{1} \otimes \mathbf{T} \end{pmatrix}^\dagger \begin{pmatrix} \mathbf{F} & \mathbf{V}^{2\text{hlp}} \\ (\mathbf{V}^{2\text{hlp}})^\dagger & \mathbf{C}^{2\text{hlp}} \end{pmatrix} \begin{pmatrix} \mathbf{1} & \mathbf{0} \\ \mathbf{0} & \mathbf{1} \otimes \mathbf{T} \end{pmatrix} \quad (3.127)$$

$$= \begin{pmatrix} \mathbf{F} & \mathbf{V}^{2\text{hlp}} (\mathbf{1} \otimes \mathbf{T}) \\ (\mathbf{1} \otimes \mathbf{T})^\dagger (\mathbf{V}^{2\text{hlp}})^\dagger & (\mathbf{1} \otimes \mathbf{T})^\dagger \mathbf{C}^{2\text{hlp}} (\mathbf{1} \otimes \mathbf{T}) \end{pmatrix}. \quad (3.128)$$

But now let us try evaluating the term $(\mathbf{1} \otimes \mathbf{T})^\dagger \mathbf{C}^{2\text{hlp}} (\mathbf{1} \otimes \mathbf{T})$ in the dRPA case. We have

$$(\mathbf{1} \otimes \mathbf{T})^\dagger \mathbf{C}^{2\text{hlp}} (\mathbf{1} \otimes \mathbf{T}) = (\mathbf{1} \otimes \mathbf{T})^\dagger (\epsilon^{1\text{ h}} \otimes \mathbf{1} + \mathbf{1} \otimes (-\mathbf{M}^{1/2})) (\mathbf{1} \otimes \mathbf{T}) \quad (3.129)$$

$$= (\mathbf{1} \otimes \mathbf{T})^\dagger (\epsilon^{1\text{ h}} \otimes \mathbf{1}) (\mathbf{1} \otimes \mathbf{T}) + (\mathbf{1} \otimes \mathbf{T})^\dagger (\mathbf{1} \otimes (-\mathbf{M}^{1/2})) (\mathbf{1} \otimes \mathbf{T}) \quad (3.130)$$

$$= \epsilon^{1\text{ h}} \otimes \mathbf{T}^\dagger \mathbf{T} + \mathbf{1} \otimes \underbrace{\left(\mathbf{T}^\dagger (-\mathbf{M}^{1/2}) \mathbf{T} \right)}_{-\mathbf{\Omega}} \quad (3.131)$$

$$(3.132)$$

Next, let us consider the product $\mathbf{V}^{2\text{hlp}} (\mathbf{1} \otimes \mathbf{T})$. We have

$$\mathbf{V}^{2\text{hlp}} (\mathbf{1} \otimes \mathbf{T}) = \sum_{ia} (pk|ia) (X_{ia}^v + Y_{ia}^v) \Omega_{ia;v}^{1/2} \underbrace{\sum_{jb} (A_{ia,jb} - B_{ia,jb})^{-1/2}}_{\Delta_{ia}^{-1/2}} \quad (3.133)$$

$$(3.134)$$

So we have

$$\mathbf{H}' = \begin{pmatrix} \mathbf{F} & \sum_{ia} (pk|ia) (X_{ia}^v + Y_{ia}^v) \Omega_{ia;v}^{1/2} \Delta_{ia}^{-1/2} \\ \sum_{jb} (pk|jb)^\dagger (X_{jb}^v + Y_{jb}^v)^\dagger \Omega_{jb;v}^{1/2} \Delta_{jb}^{-1/2} & \epsilon^{1\text{ h}} \oplus_{\text{kron}} -\mathbf{\Omega} \end{pmatrix} \quad (3.135)$$

Now consider a second similarity transform of $\mathbf{U}'' = \mathbf{1} \oplus \left(\mathbf{1} \otimes \left(\frac{\Delta_{lc}}{\Omega_{lc;v}} \right)^{1/2} \right)$, which gives us

$$\mathbf{H}'' = \mathbf{U}''^\dagger \mathbf{H}' \mathbf{U}'' \quad (3.136)$$

$$= \begin{pmatrix} \mathbf{F} & \sum_{ia} (pk|ia) (X_{ia}^v + Y_{ia}^v) \\ \sum_{jb} (pk|jb)^\dagger (X_{jb}^v + Y_{jb}^v)^\dagger & \left(\mathbf{1} \otimes \left(\frac{\Delta_{lc}}{\Omega_{lc;v}} \right)^{1/2} \right)^\dagger (\epsilon^{1\text{ h}} \oplus_{\text{kron}} \mathbf{T}^\dagger (-\mathbf{M}^{1/2}) \mathbf{T}) \left(\mathbf{1} \otimes \left(\frac{\Delta_{lc}}{\Omega_{lc;v}} \right)^{1/2} \right) \end{pmatrix} \quad (3.137)$$

Just considering the auxiliary term gives

$$\left(\mathbf{1} \otimes \left(\frac{\Delta_{lc}}{\Omega_{lc;v}} \right)^{1/2} \right)^\dagger (\epsilon^{1\text{ h}} \oplus_{\text{kron}} \mathbf{T}^\dagger (-\mathbf{M}^{1/2}) \mathbf{T}) \left(\mathbf{1} \otimes \left(\frac{\Delta_{lc}}{\Omega_{lc;v}} \right)^{1/2} \right) \quad (3.138)$$

$$= \left(\mathbf{1} \otimes \left(\frac{\Delta_{lc}}{\Omega_{lc;v}} \right)^{1/2} \right)^\dagger (\epsilon^{1\text{ h}} \otimes \mathbf{1} + \mathbf{1} \otimes \mathbf{T}^\dagger (-\mathbf{M}^{1/2}) \mathbf{T}) \left(\mathbf{1} \otimes \left(\frac{\Delta_{lc}}{\Omega_{lc;v}} \right)^{1/2} \right) \quad (3.139)$$

$$= \epsilon^{1\text{ h}} \otimes \frac{\Delta_{lc}}{\Omega_{lc;v}} + \mathbf{1} \otimes \left(\mathbf{T} \left(\frac{\Delta_{lc}}{\Omega_{lc;v}} \right)^{1/2} \right)^\dagger (-\mathbf{M}^{1/2}) \left(\mathbf{T} \left(\frac{\Delta_{lc}}{\Omega_{lc;v}} \right)^{1/2} \right) \quad (3.140)$$

$$(3.141)$$

So \mathbf{T} are eigenvectors of the matrix \mathbf{M} , with eigenvalues Ω^2 . Is there any alternate choice of \mathbf{M} that would massage this into the desired form of $\epsilon^{1\text{ h}} \oplus_{\text{kron}} (-\Omega)$? This would only work if we could assume that $\left(\frac{\Omega_{ia;v}}{\Delta_{ia}} \right)^{1/2} \approx 1$.

Evaluating the matrix-vector products

Now, we can define a vector $\mathbf{R} = (r_i, r_a, r_{i[jb]}, r_{[jb]a})$. Application of the Hamiltonian to this vector gives us the matrix-vector product $\mathbf{H}'\mathbf{R} = \boldsymbol{\sigma}$, where $\boldsymbol{\sigma} = (\sigma_i, \sigma_a, \sigma_{i[jb]}, \sigma_{[jb]a})$. So the one body matrix vector products are the same as in the dTDA case

$$\sigma_i = \sum_j f_{ij} r_j + \sum_b f_{ib} r_b + \sum_{klc} \langle i c | k l \rangle r_{k[lc]} + \sum_{kcd} \langle i k | d c \rangle r_{[kc]d}, \quad (3.142)$$

$$\sigma_a = \sum_j f_{aj} r_j + \sum_b f_{ab} r_b + \sum_{klc} \langle a c | k l \rangle r_{k[lc]} + \sum_{kcd} \langle a k | d c \rangle r_{[kc]d}, \quad (3.143)$$

$$(3.144)$$

For the two-body matrix vector products, we have

$$\sigma_{i[ja]} = \sum_k \langle k a | i j \rangle r_k + \sum_b \langle b a | i j \rangle r_b + \sum_{klc} C_{i[ja],k[lc]}^{2\text{ h1p}} r_{i[lc]} \quad (3.145)$$

Now, consider just

$$\sum_{klc} C_{i[ja],k[lc]}^{2\text{ h1p}} r_{i[lc]} = \sum_{klc} \left[\left(\epsilon_i - \mathbf{M}_{ja,lc}^{1/2} \right) \delta_{ik} r_{i[lc]} \right] = \sum_{lc} \left(\epsilon_i - \mathbf{M}_{ja,lc}^{1/2} \right) r_{i[lc]} \quad (3.146)$$

Consider now just the term

$$\sum_{lc} \mathbf{M}_{ja,lc}^{1/2} r_{i[lc]} = \sum_{lc} \left[\underbrace{\Delta_{ja}^{1/2} (\Delta_{ja} + 2(ja|lc))_{ja,lc} \Delta_{ja}^{1/2}}_{\mathbf{D}} \right]^{1/2} r_{i[lc]}. \quad (3.147)$$

Let us consider instead the similarity transformed $\tilde{\mathbf{D}} = \Delta^{-1/2} \mathbf{D} \Delta^{-1/2} = (\Delta + 2K)$. This is useful because we have $D^{1/2} = \Delta^{1/2} \tilde{D}^{1/2} \Delta^{1/2} = (\Delta + 2K)^{1/2}$ for our SPD \mathbf{D} . Now make

the change of variables $u = \Delta^{1/2}r \implies r = \Delta^{-1/2}u$. Then we have $(\Delta + 2K)\Delta^{-1/2}u = \Delta^{1/2}\left[I + \underbrace{2\Delta^{-1/2}K\Delta^{-1/2}}_L\right]u$. Again, because we are working with weak to moderately correlated systems, we can assume that L is small, and neglect it for now. So we have

$$\sum_{lc} \mathbf{M}_{ja,lc}^{1/2} r_{i[lc]} \approx \sum_{lc} \Delta^{1/2} I \Delta^{1/2} r_{i[lc]} \approx \sum_{lc} \Delta r_{i[lc]} \quad (3.148)$$

We can rewrite this as So really we have reduced the scaling to $O(O^3V^2)$. If we do a similar thing for the other term, we have

$$\sigma_{[ia]b} = \sum_j \langle j|i|ba \rangle r_j + \sum_c \langle c|i|ba \rangle r_c + \sum_{kc} \left[\epsilon_b + \mathbf{M}_{ia,kc}^{1/2} \right] r_{[kc]b} \quad (3.149)$$

which gives the scaling of $O(O^2V^3)$.

They say that $\mathbf{V}^{2\text{h1p}}$ has the elements $V_{p,k[ia]}^{2\text{h1p}} = \langle pa|ki \rangle \equiv (pk|ia)$ so we say that $\mathbf{v}_{O,O^2V}^{2\text{h1p}}$ is the first O rows of $\mathbf{V}^{2\text{h1p}}$, while $\mathbf{v}_{V,O^2V}^{2\text{h1p}}$ is the latter V rows of $\mathbf{V}^{2\text{h1p}}$.

Chapter 4

Auxiliary-boson *GW*

4.1 Constructing the Hamiltonian

The idea of this method is not to work in the MO basis, but rather to work in a basis of particle-hole excitations, which are approximated as bosons. So $\hat{a}_a^\dagger \hat{a}_i \approx \hat{b}_\nu^\dagger$ and $\hat{a}_i^\dagger \hat{a}_a \approx \hat{b}_\nu$, where in second quantization \hat{a} are fermionic and \hat{b} are bosonic operators, respectively. The drawback is that these bosonic operators no longer obey the Pauli exclusion principle; what was done above is known as the quasi-boson approximation. Then we define the electron-boson Hamiltonian as

$$\hat{H}^{\text{eB}} = \hat{H}^{\text{e}} + \hat{H}^{\text{B}} + \hat{V}^{\text{eB}} \quad (4.1)$$

where \hat{H}^{e} is the electronic Hamiltonian, \hat{H}^{B} is the bosonic Hamiltonian, and \hat{V}^{eB} is the electron-boson coupling term, given as

$$\hat{H}^{\text{e}} = \sum_{pq} f_{pq} \{ \hat{a}_p^\dagger \hat{a}_q \} \quad (4.2)$$

$$\hat{H}^{\text{B}} = \sum_{\nu\mu} A_{\nu\mu} \hat{b}_\nu^\dagger \hat{b}_\mu + \frac{1}{2} \sum_{\nu\mu} B_{\nu\mu} \left(\hat{b}_\nu^\dagger \hat{b}_\mu^\dagger + \hat{b}_\nu \hat{b}_\mu \right) \quad (4.3)$$

$$\hat{V}^{\text{eB}} = \sum_{pq,\nu} V_{pq\nu} \{ \hat{a}_p^\dagger \hat{a}_q \} \left(\hat{b}_\nu^\dagger + \hat{b}_\nu \right) \quad (4.4)$$

$A_{\nu\mu}$ and $B_{\nu\mu}$ denote the dRPA matrices, as

$$\begin{aligned} A_{\nu\mu} &= A_{ia,jb} = \delta_{ij} \delta_{ab} (\epsilon_a - \epsilon_i) + (ia|bj) \\ B_{\nu\mu} &= B_{ia,jb} = (ia|jb) \end{aligned} \quad (4.5)$$

and the electron-boson coupling term is defined as

$$V_{pq\nu} = V_{pq,ia} = (pq|ia) \quad (4.6)$$

As we will see shortly, this formalism has the ability to introduce the desired RPA screening. But the connection to Booth's ED is already clear; the physical space is represented by the electronic Hamiltonian, the auxiliary space by the bosonic Hamiltonian, and the coupling between them by the electron-boson coupling term. Right now the bosonic Hamiltonian

(specifically its second term) does not conserve the boson number. To remedy this, we perform a unitary transformation

$$\hat{U}^\dagger \hat{H}^{\text{eB}} \hat{U} \rightarrow \tilde{H}^{\text{eB}}. \quad (4.7)$$

4.1.1 Nature of the unitary transformation

First consider what the bosonic Hamiltonian looks like when expressed in the bosonic basis $\mathbf{b} = (\hat{b}_1, \hat{b}_2, \dots)$ as

$$\hat{H}^{\text{B}}(\hat{b}, \hat{b}^\dagger) = -\frac{1}{2} \text{tr} \mathbf{A} + \frac{1}{2} \begin{pmatrix} \mathbf{b}^\dagger & \mathbf{b} \end{pmatrix} \begin{pmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{B} & \mathbf{A} \end{pmatrix} \begin{pmatrix} \mathbf{b} \\ \mathbf{b}^\dagger \end{pmatrix} \quad (4.8)$$

$$= -\frac{1}{2} \text{tr} \mathbf{A} + \frac{1}{2} \begin{pmatrix} \mathbf{b}^\dagger & \mathbf{b} \end{pmatrix} \begin{pmatrix} \mathbf{A}\mathbf{b} + \mathbf{B}\mathbf{b}^\dagger \\ \mathbf{B}\mathbf{b} + \mathbf{A}\mathbf{b}^\dagger \end{pmatrix} \quad (4.9)$$

$$= -\frac{1}{2} \text{tr} \mathbf{A} + \frac{1}{2} [\mathbf{b}^\dagger \mathbf{A}\mathbf{b} + \mathbf{b}^\dagger \mathbf{B}\mathbf{b}^\dagger + \mathbf{b}\mathbf{B}\mathbf{b} + \mathbf{b}\mathbf{A}\mathbf{b}^\dagger] \quad (4.10)$$

$$= \mathbf{b}^\dagger \mathbf{A}\mathbf{b} + \frac{1}{2} [\mathbf{b}^\dagger \mathbf{B}\mathbf{b}^\dagger + \mathbf{b}\mathbf{B}\mathbf{b}] + \mathbf{0} \quad (4.11)$$

$$= \sum_{\nu\mu} A_{\nu\mu} \hat{b}_\nu^\dagger \hat{b}_\mu + \frac{1}{2} \sum_{\nu\mu} B_{\nu\mu} (\hat{b}_\nu^\dagger \hat{b}_\mu^\dagger + \hat{b}_\nu \hat{b}_\mu) \quad (4.12)$$

Going from 4.10 to 4.11, we used the fact that the final term needs to be put into normal order so we can do $\mathbf{b}\mathbf{A}\mathbf{b}^\dagger = \sum_{\mu\nu} A_{\mu\nu} b_\mu b_\nu^\dagger = \sum_{\mu\nu} A_{\mu\nu} (b_\nu^\dagger b_\mu + \delta_{\mu\nu}) = \mathbf{b}^\dagger \mathbf{A}\mathbf{b} + \text{Tr}(\mathbf{A})$. In the above we have showed equivalence to the previously defined form in 4.3. Within this representation of the bosonic Hamiltonian in the bosonic basis, in 4.8, we recognize the appearance of the RPA matrix. From 4.8, we can obtain a diagonalized form

$$\hat{H}^{\text{B}}(\bar{\mathbf{b}}, \bar{\mathbf{b}}^\dagger) = -\frac{1}{2} \text{tr} \mathbf{A} + \frac{1}{2} \begin{pmatrix} \bar{\mathbf{b}}^\dagger & \bar{\mathbf{b}} \end{pmatrix} \begin{pmatrix} \Omega \mathbf{1} & 0 \\ 0 & \Omega \mathbf{1} \end{pmatrix} \begin{pmatrix} \bar{\mathbf{b}} \\ \bar{\mathbf{b}}^\dagger \end{pmatrix} \quad (4.13)$$

through a redefinition of the bosonic operators as

$$\begin{pmatrix} \bar{\mathbf{b}} \\ \bar{\mathbf{b}}^\dagger \end{pmatrix} = \begin{pmatrix} \mathbf{X} & -\mathbf{Y} \\ -\mathbf{Y} & \mathbf{X} \end{pmatrix}^T \begin{pmatrix} \mathbf{b} \\ \mathbf{b}^\dagger \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} \mathbf{b} \\ \mathbf{b}^\dagger \end{pmatrix} = \begin{pmatrix} \mathbf{X} & \mathbf{Y} \\ \mathbf{Y} & \mathbf{X} \end{pmatrix} \begin{pmatrix} \bar{\mathbf{b}} \\ \bar{\mathbf{b}}^\dagger \end{pmatrix}. \quad (4.14)$$

Effect on the bosonic Hamiltonian

Now by expanding, we see

$$\hat{H}^B(\bar{\mathbf{b}}, \bar{\mathbf{b}}^\dagger) = -\frac{1}{2} \text{tr} \mathbf{A} + \frac{1}{2} (\bar{\mathbf{b}}^\dagger \bar{\mathbf{b}}) \begin{pmatrix} \Omega \mathbf{1} & 0 \\ 0 & \Omega \mathbf{1} \end{pmatrix} \begin{pmatrix} \bar{\mathbf{b}} \\ \bar{\mathbf{b}}^\dagger \end{pmatrix} \quad (4.15)$$

$$= -\frac{1}{2} \text{tr} \mathbf{A} + \frac{1}{2} \begin{pmatrix} \bar{\mathbf{b}}^\dagger & \bar{\mathbf{b}} \end{pmatrix} \begin{pmatrix} \Omega \bar{\mathbf{b}} \\ \Omega \bar{\mathbf{b}}^\dagger \end{pmatrix} \quad (4.16)$$

$$= -\frac{1}{2} \text{tr} \mathbf{A} + \frac{1}{2} \left[\bar{\mathbf{b}}^\dagger \Omega \bar{\mathbf{b}} + \underbrace{\bar{\mathbf{b}} \Omega \bar{\mathbf{b}}^\dagger}_{\bar{b}^\dagger \Omega \bar{b} + \text{Tr}(\Omega)} \right] \quad (4.17)$$

$$= \bar{\mathbf{b}}^\dagger \Omega \bar{\mathbf{b}} + \frac{1}{2} \text{Tr}(\Omega - \mathbf{A}) \quad (4.18)$$

$$= \sum_{\nu} \Omega_{\nu} \bar{b}_{\nu}^{\dagger} \bar{b}_{\nu} + E_{\text{RPA}}^c \quad (4.19)$$

so we removed the non-boson conserving quality of the bosonic Hamiltonian (compare to 4.3).

Effect on the electron-boson coupling term

Originally, the electron-boson coupling term is given as

$$\hat{V}^{\text{eB}} = \sum_{pq, \nu} V_{pq, \nu} \{ \hat{a}_p^{\dagger} \hat{a}_q \} \left(\hat{b}_{\nu}^{\dagger} + \hat{b}_{\nu} \right) \quad (4.20)$$

Here, we will use that the redefinition of the bosonic operators such that $\hat{b}_{\nu} = \sum_{\mu} \left(\mathbf{X}_{\mu}^{\nu} \hat{\bar{b}}_{\nu} + \mathbf{Y}_{\mu}^{\nu} \hat{\bar{b}}_{\nu}^{\dagger} \right)$ and $\hat{b}_{\nu}^{\dagger} = \sum_{\mu} \left(\mathbf{X}_{\mu}^{\nu} \hat{\bar{b}}_{\nu}^{\dagger} + \mathbf{Y}_{\mu}^{\nu} \hat{\bar{b}}_{\nu} \right)$, which gives $\hat{b}_{\nu} + \hat{b}_{\nu}^{\dagger} = \sum_{\mu} (\mathbf{X}_{\mu}^{\nu} + \mathbf{Y}_{\mu}^{\nu}) \left(\hat{\bar{b}}_{\nu} + \hat{\bar{b}}_{\nu}^{\dagger} \right)$, so after we plug in

$$\hat{V}^{\text{eB}} = \sum_{pq, \nu} V_{pq, \nu} \{ \hat{a}_p^{\dagger} \hat{a}_q \} \left(\sum_{\mu} (\mathbf{X}_{\mu}^{\nu} + \mathbf{Y}_{\mu}^{\nu}) \right) \left(\hat{\bar{b}}_{\nu} + \hat{\bar{b}}_{\nu}^{\dagger} \right) \quad (4.21)$$

$$= \sum_{pq, \nu} W_{pq, \nu} \{ \hat{a}_p^{\dagger} \hat{a}_q \} (\bar{b}_{\nu} + \bar{b}_{\nu}^{\dagger}) \quad (4.22)$$

where now we had identified the RPA screened Coulomb interaction $W_{pq, \nu} = V_{pq, \nu} \sum_{\mu} (\mathbf{X}_{\mu}^{\nu} + \mathbf{Y}_{\mu}^{\nu})$.

4.2 Connection to Booth supermatrix

We then build the supermatrices \mathbf{H} and \mathbf{S} with matrix elements,

$$H_{IJ} = \langle 0_{\text{F}} 0_{\text{B}} | \left[C_I, \left[\tilde{H}^{\text{eB}}, C_J^{\dagger} \right] \right] | 0_{\text{F}} 0_{\text{B}} \rangle$$

$$S_{IJ} = \langle 0_{\text{F}} 0_{\text{B}} | \left[C_I, C_J^{\dagger} \right] | 0_{\text{F}} 0_{\text{B}} \rangle$$

where $\{C_I^\dagger\} = \left\{ \underbrace{a_i}_{1h}, \underbrace{a_a}_{1p}, \underbrace{a_i b_\nu^\dagger}_{2h1p}, \underbrace{a_a b_\nu}_{1p2p} \right\}$ and $|0\rangle_F$ and $|0\rangle_B$ are the Fermi and boson vacuums.

Then constructing $-\mathbf{S}^{-1}\mathbf{H}$ yields Booth's ED, which is

$$\mathbf{H}^{G_0 W_0} = \begin{pmatrix} \mathbf{F} & \mathbf{W}^< & \mathbf{W}^> \\ \mathbf{W}^{\dagger <} & \mathbf{d}^< & \mathbf{0} \\ \mathbf{W}^{\dagger >} & \mathbf{0} & \mathbf{d}^> \end{pmatrix} \quad (4.23)$$

where \mathbf{F} is the Fock matrix, $\mathbf{W}^<$ and $\mathbf{W}^>$ are the lesser and greater components of the RPA screened Coulomb interaction, defined as

$$W_{pk\nu}^< = \sum_{ia} (pk|ia) (X_{ia}^\nu + Y_{ia}^\nu) \quad \text{and} \quad W_{pc\nu}^> = \sum_{ia} (pc|ia) (X_{ia}^\nu + Y_{ia}^\nu) \quad (4.24)$$

and the auxiliary blocks $\mathbf{d}^<$ and $\mathbf{d}^>$ are defined as

$$d_{k\nu,l\nu'}^< = (\epsilon_k - \Omega_\nu) \delta_{k,l} \delta_{\nu,\nu'} \quad \text{and} \quad d_{c\nu,d\nu'}^> = (\epsilon_c + \Omega_\nu) \delta_{c,d} \delta_{\nu,\nu'} \quad (4.25)$$

4.2.1 Derivation of the supermatrices for the 2h1p sector

Overlap

Computing the matrix elements of the \mathbf{S} gives:

$$\mathbf{S} = \begin{pmatrix} \delta_{ij} & 0 & 0 & 0 \\ 0 & -\delta_{ab} & 0 & 0 \\ 0 & 0 & \delta_{ij} \delta_{\nu\nu'} & 0 \\ 0 & 0 & 0 & -\delta_{ab} \delta_{\nu\nu'} \end{pmatrix} \quad (4.26)$$

H takes more care.

Physical

$$H_{ij} = \langle 0_F 0_B | \left[a_i^\dagger, \left[\hat{H}^{eB}, a_j \right] \right] | 0_F 0_B \rangle = \langle 0_F 0_B | \left[a_i^\dagger, \left[\hat{H}^e, a_j \right] \right] | 0_F 0_B \rangle \quad (4.27)$$

We can make this simplification because the electronic operators commute with all bosonic operators. Now

$$[\hat{H}^e, a_j] = \sum_{pq} f_{pq} [a_p^\dagger a_q, a_j] = \sum_{pq} f_{pq} (a_p^\dagger [a_q, a_j] + [a_p^\dagger, a_j] a_q) \quad (4.28)$$

$$= \sum_{pq} f_{pq} (a_p^\dagger a_q a_j - a_p^\dagger a_j a_q + a_p^\dagger a_j a_q - a_j a_p^\dagger a_q) \quad (4.29)$$

$$[a_i^\dagger, [\hat{H}^e, a_j]] = \sum_{pq} f_{pq} [a_i^\dagger, (a_p^\dagger a_q a_j - a_j a_p^\dagger a_q)] \quad (4.30)$$

$$= \sum_{pq} f_{pq} ([a_i^\dagger, a_p^\dagger a_q a_j] - [a_i^\dagger, a_j a_p^\dagger a_q]) \quad (4.31)$$

$$= \sum_{pq} f_{pq} (a_i^\dagger a_p^\dagger a_q a_j - a_p^\dagger a_q a_j a_i^\dagger - a_i^\dagger a_j a_p^\dagger a_q + a_j a_p^\dagger a_q a_i^\dagger) \quad (4.32)$$

$$a_i^\dagger a_p^\dagger a_q a_j = \overline{a_i^\dagger a_p^\dagger a_q a_j} + \overline{a_i^\dagger a_p^\dagger a_q a_j} = -\delta_{iq} \delta_{jp} + \cancel{\delta_{ij} \delta_{pq}} \quad (4.33)$$

$$a_p^\dagger a_q a_j a_i^\dagger = 0 \quad (4.34)$$

$$a_i^\dagger a_j a_p^\dagger a_q = \overline{a_i^\dagger a_j a_p^\dagger a_q} + \overline{a_i^\dagger a_j a_p^\dagger a_q} = 0 + \cancel{\delta_{ij} \delta_{pq}} \quad (4.35)$$

$$a_j a_p^\dagger a_q a_i^\dagger = 0 \quad (4.36)$$

$$= - \sum_{pq} f_{pq} \delta_{iq} \delta_{jp} = -f_{ji} \quad (4.37)$$

So $H_{ij} = -f_{ji}$ and then $\boxed{(-S^{-1}H)_{ij} = +\delta_{ij} f_{ji} = f_{ii} = \epsilon_i}$.

Auxiliary

$$H_{i\nu j\nu'} = \langle 0_F 0_B | \left[a_i^\dagger b_\nu, \left[\hat{H}^{eB}, a_j b_{\nu'}^\dagger \right] \right] | 0_F 0_B \rangle = \langle 0_F 0_B | \left[a_i^\dagger b_\nu, \left[\hat{H}^e + \hat{H}^B + \hat{V}^{eB}, a_j b_{\nu'}^\dagger \right] \right] | 0_F 0_B \rangle \quad (4.38)$$

$$(4.39)$$

First

$$[\hat{H}^e, a_j b_\mu^\dagger] = \sum_{pq} f_{pq} [a_p^\dagger a_q, a_j b_\mu^\dagger] = \sum_{pq} f_{pq} [a_p^\dagger a_q a_j - a_j a_p^\dagger a_q] b_\mu^\dagger \quad (4.40)$$

$$[a_i^\dagger b_\nu, [\hat{H}^e, a_j b_\mu^\dagger]] = [a_i^\dagger b_\nu, \sum_{pq} f_{pq} [a_p^\dagger a_q a_j - a_j a_p^\dagger a_q] b_\mu^\dagger] = \sum_{pq} f_{pq} [a_i^\dagger, a_p^\dagger a_q a_j - a_j a_p^\dagger a_q] [b_\nu, b_\mu^\dagger] \quad (4.41)$$

$$= \delta_{\nu\mu} \sum_{pq} f_{pq} \left(a_i^\dagger a_p^\dagger a_q a_j - a_p^\dagger a_q a_j a_i^\dagger - a_i^\dagger a_j a_p^\dagger a_q + a_j a_p^\dagger a_q a_i^\dagger \right) \quad (4.42)$$

$$a_i^\dagger a_p^\dagger a_q a_j = \overline{a_i^\dagger a_p^\dagger a_q a_j} + \overline{a_i^\dagger a_p^\dagger a_q a_j} = -\underbrace{\delta_{iq} \delta_{jp}}_{q,p \in O} + \cancel{\delta_{ij} \delta_{pq}} \quad (4.43)$$

$$a_p^\dagger a_q a_j a_i^\dagger = 0 \quad (4.44)$$

$$a_i^\dagger a_j a_p^\dagger a_q = \overline{a_i^\dagger a_j a_p^\dagger a_q} + \overline{a_i^\dagger a_j a_p^\dagger a_q} = 0 + \cancel{\delta_{ij} \delta_{pq}} \quad (4.45)$$

$$a_p^\dagger a_j a_q a_i^\dagger = 0 \quad (4.46)$$

$$(4.47)$$

So $[a_i^\dagger b_\nu, [\hat{H}^e, a_j b_\mu^\dagger]] = -\delta_{\nu\mu} f_{ji}$. Next

$$[\hat{H}^B, a_j b_\mu^\dagger] = \left[\sum_\nu \Omega_\nu b_\nu^\dagger b_\nu + E_{\text{RPA}}^c, a_j b_\mu^\dagger \right] = \sum_\nu \Omega_\nu a_j [b_\nu^\dagger b_\nu, b_\mu^\dagger] = \sum_\nu \Omega_\nu a_j b_\nu^\dagger [b_\nu, b_\mu^\dagger] = \Omega_\mu a_j b_\mu^\dagger \quad (4.48)$$

$$[a_i^\dagger b_\nu, [\hat{H}^B, a_j b_\mu^\dagger]] = \Omega_\mu [a_i^\dagger b_\nu, a_j b_\mu^\dagger] = \Omega_\mu [a_i^\dagger, a_j] [b_\nu, b_\mu^\dagger] = \delta_{ij} \delta_{\nu\mu} \Omega_\mu \quad (4.49)$$

$$(4.50)$$

So $[a_i^\dagger b_\nu, [\hat{H}^B, a_j b_\mu^\dagger]] = \delta_{ij} \delta_{\nu\mu} \Omega_\mu$. last

$$[a_i^\dagger b_\nu, [\hat{V}^{eB}, a_j b_{\nu'}^\dagger]] = 0 \quad (4.51)$$

because we notice that in the coupling term, the number of bosons is not conserved. So $H_{i\nu j\nu'} = \delta_{\nu\nu'} (\delta_{ij} \Omega_{\nu'} - f_{ji})$ and then $\boxed{(-S^{-1}H)_{i\nu j\nu'} = -\delta_{ij} (\delta_{\nu\nu'} (\delta_{ij} \Omega_\nu - f_{ji})) = \delta_{ij} \delta_{\nu\nu'} (\epsilon_i - \Omega_\nu)}$.

Coupling

$$H_{i,p\nu} = \langle 0_F 0_B | \left[a_i^\dagger, \left[\hat{H}^{eB}, a_p b_\nu^\dagger \right] \right] | 0_F 0_B \rangle = \langle 0_F 0_B | \left[a_i^\dagger, \left[\hat{V}^{eB}, a_p b_\nu^\dagger \right] \right] | 0_F 0_B \rangle \quad (4.52)$$

Note that we have neglected the electronic and bosonic Hamiltonians, because using them

in this arrangement will not conserve the number of bosons. So we have

$$[V^{eB}, a_p b_\nu^\dagger] = \sum_{rs, \nu'} W_{rs, \nu'} [a_r^\dagger a_s (b_{\nu'} + b_{\nu'}^\dagger), a_p b_\nu^\dagger] = \sum_{rs, \nu'} W_{rs, \nu'} [a_r^\dagger a_s, a_p] [b_{\nu'}, b_\nu^\dagger] \quad (4.53)$$

$$= \sum_{rs} W_{rs, \nu} (a_r^\dagger a_s a_p - a_p a_r^\dagger a_s) \quad (4.54)$$

$$[a_i^\dagger, [\hat{V}^{eB}, a_p b_\nu^\dagger]] = \sum_{rs} W_{rs, \nu} \left[a_i^\dagger \hat{a}_r^\dagger \hat{a}_s a_p - \hat{a}_r^\dagger \hat{a}_s a_p a_i^\dagger - \left(a_i^\dagger a_p a_r^\dagger a_s - a_p a_r^\dagger a_s a_i^\dagger \right) \right] \quad (4.55)$$

$$a_i^\dagger \hat{a}_r^\dagger \hat{a}_s a_p = \overbrace{a_i^\dagger a_r^\dagger a_s a_p} + \overbrace{a_i^\dagger a_r^\dagger a_s a_p} = -\underbrace{\delta_{is} \delta_{rp}}_{s \in O} + \cancel{\delta_{ip} \delta_{rs}} \quad (4.56)$$

$$\hat{a}_r^\dagger \hat{a}_s a_p a_i^\dagger = \overbrace{\hat{a}_r^\dagger a_s a_p a_i^\dagger} + \overbrace{\hat{a}_r^\dagger a_s a_p a_i^\dagger} = 0 \quad (4.57)$$

$$a_i^\dagger a_p a_r^\dagger a_s = \overbrace{a_i^\dagger a_p a_r^\dagger a_s} + \overbrace{a_i^\dagger a_p a_r^\dagger a_s} = \cancel{\delta_{ip} \delta_{rs}} + 0 \quad (4.58)$$

$$a_p a_r^\dagger a_s a_i^\dagger = 0 \quad (4.59)$$

$$(4.60)$$

So we can write $H_{i, p\nu} = -W_{pi, \nu} = -W_{ip, \nu}$ because of the permutational symmetry of the ERIs. Then $\boxed{(-S^{-1}H)_{p, i\nu} = +W_{pi, \nu}}$.

Chapter 5

BSE Notes

5.1 The standard canon

To get the particle-hole response function L , we need to solve the Dyson equation, which reads

$$\frac{\partial G(1, 1')}{\partial U(2', 2)} \equiv L(1, 2; 1', 2') = L_0(1, 2; 1', 2') + \int d(3456) L_0(1, 4; 1', 3) \Xi^{\text{eh}}(3, 5; 4, 6) L(6, 2; 5, 2') \quad (5.1)$$

G is the one-particle Green's function and U is the fictitious nonlocal potential due to Schwinger. $L_0(1, 2; 1', 2') = G(1, 2') G(2, 1')$ is the non-interacting eh propagator and the eh kernel Ξ^{eh} is defined as

$$i\Xi^{\text{eh}}(3, 5; 4, 6) = v(3, 6)\delta(3, 4)\delta(5, 6) + i\frac{\delta\Sigma(3, 4)}{\delta G(6, 5)} \quad (5.2)$$

5.1.1 TD-DFT Similarity

In the TD-DFT framework, we have the Dyson equation for the density-density response function χ :

$$\frac{\partial\rho(1)}{\partial U(2)} \equiv \chi(1, 2) = \chi_0(1, 2) + \int d34\chi_0(1, 3)\Xi^{\text{DFT}}(3, 4)\chi(4, 2) \quad (5.3)$$

ρ is the density. χ_0 is the non-interacting density-density response function and Ξ^{DFT} is the DFT kernel given by

$$\Xi^{\text{DFT}}(3, 4) = v(3, 4) + \frac{\partial V^{\text{xc}}(3)}{\partial\rho(4)} \quad (5.4)$$

It is worth noting that $\chi(1, 2) = -iL(1, 2; 1^+, 2^+)$ with $\rho(1) = -iG(1, 1^+)$, with the $+$ indicating a slightly shifted time to preserve causality. So the Dyson equation for L reduces to the Dyson equation for χ once the appropriate contractions have been performed. Earlier in the year, I was able to show that

$$\chi_{\text{RPA}}(\omega) = \left[\begin{pmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{B} & \mathbf{A} \end{pmatrix} + \omega \begin{pmatrix} \mathbf{I} & 0 \\ 0 & -\mathbf{I} \end{pmatrix} \right]^{-1} \quad (5.5)$$

$$(5.6)$$

So presumably, we can also write

$$L(\omega) = \left[\begin{pmatrix} \tilde{\mathbf{A}} & \tilde{\mathbf{B}} \\ \tilde{\mathbf{B}} & \tilde{\mathbf{A}} \end{pmatrix} + \omega \begin{pmatrix} \mathbf{I} & 0 \\ 0 & -\mathbf{I} \end{pmatrix} \right]^{-1} \quad (5.7)$$

where now the matrices $\tilde{\mathbf{A}}$ and $\tilde{\mathbf{B}}$ are defined in the direct approximation as

$$\tilde{A}_{\mu\nu} \equiv \tilde{A}_{ai,bj} = (\epsilon_a^{GW} - \epsilon_i^{GW}) \delta_{ab} \delta_{ij} + (ai|jb) - \Xi_{ab,ji}^c(\omega) \quad (5.8)$$

$$\tilde{B}_{\mu\nu} \equiv \tilde{B}_{ai,bj} = (ai|bj) - \Xi_{bi,aj}^c(\omega) \quad (5.9)$$

So we know that we want to solve for the eigenvalues of the matrix

$$\begin{pmatrix} \tilde{\mathbf{A}} & \tilde{\mathbf{B}} \\ \tilde{\mathbf{B}} & \tilde{\mathbf{A}} \end{pmatrix} = \begin{pmatrix} \mathbf{X} & -\mathbf{Y} \\ -\mathbf{Y} & \mathbf{X} \end{pmatrix} \begin{pmatrix} \Omega\mathbf{1} & 0 \\ 0 & \Omega\mathbf{1} \end{pmatrix} \begin{pmatrix} \mathbf{X} & -\mathbf{Y} \\ -\mathbf{Y} & \mathbf{X} \end{pmatrix} \quad (5.10)$$

5.1.2 The GW formulation

In the GW approximation, eh kernel takes on the simpler form

$$i\Xi_{GW}^{\text{eh}}(3, 5; 4, 6) = v(3, 6)\delta(3, 4)\delta(5, 6) - W(3^+, 4)\delta(3, 6)\delta(4, 5) \quad (5.11)$$

This follows when we approximate Σ by the GW self-energy:

$$\Sigma(1, 2) \approx \Sigma^{GW}(1, 2) = iG(1, 2)W(2, 1^+) \implies i\frac{\delta\Sigma(3, 4)}{\delta G(6, 5)} \approx i\frac{\delta\Sigma^{GW}(3, 4)}{\delta G(6, 5)} = -W(3^+, 4)\delta(3, 6)\delta(4, 5) \quad (5.12)$$

The \mathbf{A} and \mathbf{B} matrices become:

$$A_{ai,bj} = (\epsilon_a - \epsilon_i) \delta_{ab} \delta_{ij} + (ai|jb) - W_{ab,ji}(\omega) \quad (5.13)$$

$$B_{ai,bj} = (ai|bj) - W_{bi,aj}(\omega) \quad (5.14)$$

It is customary to make the static approximation to the screened Coulomb potential, i.e. $W_{ab,ji}(\omega) \approx W_{ab,ji}(\omega = 0)$. Because the super matrix formulation for GW was so successful at obtaining all QPEs without having to solve a QP equation, I wonder if formulating the BSE in a supermatrix form will enable us to discard this static approximation.

5.2 Berkelbach TDA BSE

Here the BSE is defined as

$$\mathcal{A}(\omega) \equiv A_{ia,jb} - K_{ab,ij}^{(p)}(\omega) \quad (5.15)$$

$$(5.16)$$

where

$$A_{ia,jb} = (E_a - E_i) \delta_{ij} \delta_{ab} + \kappa(ia|jb) - (ab|ij) \quad (5.17)$$

$$K_{abij}^{(p)}(\omega) = 2 \sum_m^{\Omega_m > 0} (ij|\rho_m) (ab|\rho_m) \left[\frac{1}{\omega - (E_b - E_i) - \Omega_m} + \frac{1}{\omega - (E_a - E_j) - \Omega_m} \right] \quad (5.18)$$

$$(5.19)$$

with κ set to 2 for singlets and 0 for triplets.

We want to show that the spectrum of the unfolded matrix \mathcal{H} is equivalent to that of the Bethe-Salpeter equation (BSE) in the Tamm-Dancoff approximation (TDA). The unfolded Hamiltonian is given by

$$\mathcal{H} = \begin{pmatrix} \mathbf{A} & -\mathbf{V}^e & -\mathbf{V}^h \\ (\mathbf{V}^h)^\dagger & \mathbf{D} & \mathbf{0} \\ (\mathbf{V}^e)^\dagger & \mathbf{0} & \mathbf{D} \end{pmatrix} \quad (5.20)$$

The physical block has already been defined; the rest is:

$$\mathbf{D} = [-\mathbf{E}_{\text{occ}}] \oplus_{\text{kron}} \mathbf{E}_{\text{vir}} \oplus_{\text{kron}} \mathbf{S} \quad (5.21)$$

$$V_{ia,ldkc}^h = \sqrt{2} (il|kc) \delta_{ad} \quad (5.22)$$

$$V_{ia,ldkc}^e = \sqrt{2} (kc|ad) \delta_{il} \quad (5.23)$$

Here, \mathbf{S} is the direct RPA matrix in the TDA, defined as

$$S_{ia,jb} = (\epsilon_a - \epsilon_i) \delta_{ij} \delta_{ab} + (ia|jb), \quad (5.24)$$

\mathbf{E}_{occ} and \mathbf{E}_{vir} are diagonal matrices containing the GW QPEs of the occupied and virtual orbitals, respectively. The dimensions of the blocks are as follows: \mathbf{A} is $OV \times OV$, \mathbf{V}^e is $OV \times O^2V^2$, \mathbf{V}^h is $OV \times O^2V^2$, and \mathbf{D} is $O^2V^2 \times O^2V^2$, where O and V are the numbers of occupied and virtual orbitals, respectively.

Comment on system-bath distinction here

The idea is that here we are effectively treating the \mathbf{A} as the physical space that has only the single excitations, while \mathbf{D} is the bath space that has the double excitations. Just as in their frequency free implementation for GW in the TDA, the couplings between the physical and bath spaces, are just defined in terms of the two-electron integrals.

By downfolding the double excitations into the space of single excitations, we obtain the frequency-dependent effective matrix:

$$\mathcal{A}(\omega) = \mathbf{A} - \mathbf{V}^e(\omega\mathbf{I} - \mathbf{D})^{-1}(\mathbf{V}^h)^\dagger - \mathbf{V}^h(\omega\mathbf{I} - \mathbf{D})^{-1}(\mathbf{V}^e)^\dagger \quad (5.25)$$

Start by working out the eigenvalues of \mathbf{D} .

$$\mathbf{D} = -\mathbf{E}_O \otimes \mathbf{I}_V \otimes \mathbf{I}_{OV} + \mathbf{I}_O \otimes \mathbf{E}_V \otimes \mathbf{I}_{OV} + \mathbf{I}_O \otimes \mathbf{I}_V \otimes \mathbf{A}_{OV} \quad (5.26)$$

Now define the unitary transformation $\tilde{\mathbf{X}} = \mathbf{I}_O \otimes \mathbf{I}_V \otimes \mathbf{X}_{OV}$, where \mathbf{X}_{OV} diagonalizes \mathbf{A}_{OV} .

The transformation is applied to the matrix \mathbf{D} as follows:

$$\tilde{\mathbf{X}}^\dagger \mathbf{D} \tilde{\mathbf{X}} = \tilde{\mathbf{X}}^\dagger (-\mathbf{E}_O \otimes \mathbf{I}_V \otimes \mathbf{I}_{OV} + \mathbf{I}_O \otimes \mathbf{E}_V \otimes \mathbf{I}_{OV} + \mathbf{I}_O \otimes \mathbf{I}_V \otimes \mathbf{A}_{OV}) \tilde{\mathbf{X}} \quad (5.27)$$

$$= \tilde{\mathbf{X}}^\dagger (-\mathbf{E}_O \otimes \mathbf{I}_V \otimes \mathbf{I}_{OV}) \tilde{\mathbf{X}} + \tilde{\mathbf{X}}^\dagger (\mathbf{I}_O \otimes \mathbf{E}_V \otimes \mathbf{I}_{OV}) \tilde{\mathbf{X}} + \tilde{\mathbf{X}}^\dagger (\mathbf{I}_O \otimes \mathbf{I}_V \otimes \mathbf{A}_{OV}) \tilde{\mathbf{X}} \quad (5.28)$$

$$= -\mathbf{E}_O \underbrace{\mathbf{I}_O^\dagger \mathbf{I}_O}_{\mathbf{I}_O} \otimes \underbrace{\mathbf{I}_V^\dagger \mathbf{I}_V}_{\mathbf{I}_V} \otimes \underbrace{\mathbf{X}^\dagger \mathbf{X}}_{\mathbf{I}_{OV}} + \underbrace{\mathbf{I}_O^\dagger \mathbf{I}_O}_{\mathbf{I}_O} \otimes \mathbf{E}_V \underbrace{\mathbf{I}_V^\dagger \mathbf{I}_V}_{\mathbf{I}_V} \otimes \underbrace{\mathbf{X}^\dagger \mathbf{X}}_{\mathbf{I}_{OV}} + \underbrace{\mathbf{I}_O^\dagger \mathbf{I}_O}_{\mathbf{I}_O} \otimes \underbrace{\mathbf{I}_V^\dagger \mathbf{I}_V}_{\mathbf{I}_V} \otimes \underbrace{\mathbf{X}^\dagger \mathbf{A} \mathbf{X}}_{\mathbf{\Omega}_{OV}} \quad (5.29)$$

$$= -\mathbf{E}_O \oplus \mathbf{E}_V \oplus \mathbf{\Omega}_{OV} \quad (5.30)$$

$$\Rightarrow \mathbf{D} = \tilde{\mathbf{X}} (-\mathbf{E}_O \oplus \mathbf{E}_V \oplus \mathbf{\Omega}_{OV}) \tilde{\mathbf{X}}^\dagger \quad (5.31)$$

$$(5.32)$$

Now we can write the spectral representation of the resolvent as

$$(\omega \mathbf{I} - \mathbf{D})^{-1} = \tilde{\mathbf{X}} [(\omega \mathbf{I} - (-\mathbf{E}_O \oplus \mathbf{E}_V \oplus \mathbf{\Omega}_{OV}))^{-1}] \tilde{\mathbf{X}}^\dagger \quad (5.33)$$

This leads to

$$K_{abij}^{(p)}(\omega) = \mathbf{V}^e (\omega \mathbf{I} - \mathbf{D})^{-1} (\mathbf{V}^h)^\dagger + \mathbf{V}^h (\omega \mathbf{I} - \mathbf{D})^{-1} (\mathbf{V}^e)^\dagger \quad (5.34)$$

$$= \frac{\mathbf{V}^e \tilde{\mathbf{X}} (\mathbf{V}^h \tilde{\mathbf{X}})^\dagger}{\omega \mathbf{I} - (-\mathbf{E}_O \oplus \mathbf{E}_V \oplus \mathbf{\Omega}_{OV})} + \frac{\mathbf{V}^h \tilde{\mathbf{X}} (\mathbf{V}^e \tilde{\mathbf{X}})^\dagger}{\omega \mathbf{I} - (-\mathbf{E}_O \oplus \mathbf{E}_V \oplus \mathbf{\Omega}_{OV})} \quad (5.35)$$

$$= 2 \sum_\nu \left(\frac{\sum_{ldkc} (kc|ad) \delta_{il} (e_l \otimes e_d \otimes X_{kc,\nu}) (\sum_{ldkc} (il|kc) \delta_{ad} (e_l \otimes e_d \otimes X_{kc,\nu}))^\dagger}{\omega - (E_b - E_i) - \Omega_\nu} \right) \quad (5.36)$$

$$+ \frac{\sum_{ldkc} (il|kc) \delta_{ad} (e_l \otimes e_d \otimes X_{kc,\nu}) (\sum_{ldkc} (kc|ad) \delta_{il} (e_l \otimes e_d \otimes X_{kc,\nu}))^\dagger}{\omega - (E_a - E_j) - \Omega_\nu} \quad (5.37)$$

$$= 2 \sum_{m, \Omega_m > 0} (ij|\rho_m) (ab|\rho_m) \left[\frac{1}{\omega - (E_b - E_i) - \Omega_m} + \frac{1}{\omega - (E_a - E_j) - \Omega_m} \right] \quad (5.38)$$

where $(pq|\rho_m) = \sum_{ia} X_{ia}^m(pq|ia)$. Not sure how to derive this. But we can write the unfolded 2p Hamiltonian with RPA screening, noting that

$$B_{ia,jb} = \kappa(ib|aj) \quad (5.39)$$

$$\mathcal{H} = \begin{pmatrix} -\mathbf{V}^e & -\mathbf{V}^h \\ (\mathbf{V}^h)^\dagger & \mathbf{D} & \mathbf{0} \\ (\mathbf{V}^e)^\dagger & \mathbf{0} & \mathbf{D} \end{pmatrix} \quad (5.40)$$

$$(5.41)$$

Now we can write the spectral decomposition

$$\Rightarrow (\omega I - D)_{ia,\nu}^{-1} = \frac{|ia, \nu\rangle \langle ia, \nu|}{\omega - (E_a - E_i) - \Omega_\nu} \quad (5.42)$$

$$(5.43)$$

where $|ia, \nu\rangle$ is the right eigenvector of \mathbf{D} defined by $e_i \otimes e_a \otimes \sum_{jb} X_{jb, \nu}$, with e_i and e_a being unit vectors in the occupied and virtual orbital spaces, respectively, and $\sum_{jb} X_{jb, \nu}$ as the excitation vector for the ν th RPA excitation in the TDA and $(pq|\rho_m) = \sum_{ia} X_{ia}^m(pq|ia)$ with

$$K_{abij}^{(p)}(\omega) \equiv \mathbf{V}^e(\omega \mathbf{I} - \mathbf{D})^{-1}(\mathbf{V}^h)^\dagger + \mathbf{V}^h(\omega \mathbf{I} - \mathbf{D})^{-1}(\mathbf{V}^e)^\dagger \quad (5.44)$$

Explicitly, the matrix elements of $\mathcal{A}(\Omega)$ are given by

$$\mathcal{A}_{ia,jb}(\Omega) = A_{ia,jb} - K_{abij}^{(p)}(\Omega) \quad (5.45)$$

$$A_{ia,jb} = (E_a - E_i) \delta_{ij} \delta_{ab} + \kappa(ia|jb) - (ab|ij) \quad (5.46)$$

where the frequency-dependent kernel is

$$K_{abij}^{(p)}(\Omega) = \frac{i}{2\pi} \int d\omega e^{-i\omega 0^+} W_{abij}^{(p)}(\omega) \left[\frac{1}{\Omega - \omega - (E_b - E_i) + i\eta} + \frac{1}{\Omega + \omega - (E_a - E_j) + i\eta} \right] \quad (5.47)$$

$$= 2 \sum_m^{\Omega_m > 0} (ij|\rho_m) (ab|\rho_m) \left[\frac{1}{\Omega - (E_b - E_i) - \Omega_m} + \frac{1}{\Omega - (E_a - E_j) - \Omega_m} \right] \quad (5.48)$$

To prove the equivalence, we need to show that the eigenvalues of the upfolded Hamiltonian \mathcal{H} correspond to the excitation energies obtained from the BSE in the TDA, i.e., the poles of the response function defined by the effective matrix $\mathcal{A}(\omega)$.

$$K_{abij}^{(p)}(\Omega) = 2 \sum_m^{\Omega_m > 0} (ij|\rho_m) (ab|\rho_m) \left[\frac{1}{\Omega - (E_b - E_i) - \Omega_m} + \frac{1}{\Omega - (E_a - E_j) - \Omega_m} \right]$$

and we have dropped $i\eta$ terms. The

5.3 A formulation in terms of supermatrices

We know the equation

$$\mathbf{L}^{-1} = \mathbf{L}_0^{-1} - \mathbf{\Xi}^{\text{eh}} \quad (5.49)$$

The excitation energies that we are trying to solve for in the Bethe-Salpeter equation are formally the poles of the reducible eh response function \mathbf{L} , so we just need to determine the eigenvalues of the RHS of the above equation. This is analogous to how we were able to determine the QPEs by finding the poles of the Green's function, which were the eigenvalues of the upfolded Hamiltonian. First consider

$$\mathbf{L}_0 = \mathbf{G} \otimes \mathbf{G} \quad (5.50)$$

$$\implies \mathbf{L}_0^{-1} = \mathbf{G}^{-1} \otimes \mathbf{G}^{-1} \quad (5.51)$$

$$= (\mathbf{H}^{GW}) \otimes (\mathbf{H}^{GW}) \quad (5.52)$$

where

$$\mathbf{H}^{GW} = \begin{pmatrix} \mathbf{F} & \mathbf{W}^< & \mathbf{W}^> \\ \mathbf{W}^{\dagger<} & \mathbf{d}^< & \mathbf{0} \\ \mathbf{W}^{\dagger>} & \mathbf{0} & \mathbf{d}^> \end{pmatrix} \quad (5.53)$$

Note that the irreducible eh response function \mathbf{L}_0 reduces to the irreducible density-density response function χ_0 , when we integrate out one space-time variable.

$$\frac{\delta \Sigma^H}{\delta \mathbf{G}} = \mathbf{v} \otimes \mathbf{I} \quad (5.54)$$

$$\frac{\delta \Sigma^x}{\delta \mathbf{G}} = -\mathbf{\Pi} (\mathbf{W} \otimes \mathbf{I}) \quad (5.55)$$

$$(5.56)$$

where $\mathbf{\Pi}$ is a permutation operator with the action of swapping one space-time index between the two spaces.

is the so-called BSE kernel.

$$\chi(1, 2) = \chi_0(1, 2) + \int d34 \chi_0(1, 3) \Xi^{\text{DFT}}(3, 4) \chi(4, 2)$$

where

$$\Xi^{\text{DFT}}(3, 4) = v(3, 4) + \frac{\partial V^{\text{xc}}(3)}{\partial \rho(4)}$$

is the TD-DFT kernel. Plugging now the GW self-energy (see eq 7), in a scheme that we label BSE@GW, leads to an approximate version of the BSE kernel

$$\begin{aligned} i\Xi^{\text{BSE}}(3, 5; 4, 6) &= v(3, 6) \delta(34) \delta(56) \\ &\quad - W(3^+, 4) \delta(36) \delta(45) \end{aligned}$$

TODO: check that in the theory we satisfy $\chi = \text{Tr } \mathbf{L}$, which is the trace of the supermatrix \mathbf{L} .
